TABLE 41.—SILICA SAND—DETAILED SUMMARY, BY STATES: 1902.

	United States.	Ohio.	Pennsylvania.
Number of quarries	26	10	16
Number of operators	20	7	[1] 13
Character of ownership:			
Individual	5	2	3
Firm	5	2	3
Incorporated company	10	3	7
Salaried officials, clerks, etc.:			
Total number	35	18	17
Total salaries	$27,228	$13,988	$13,240
General officers—			
Number	9	7	2
Salaries	$10,240	$7,040	$3,200
Superintendents, managers, foremen, surveyors, etc.—			
Number	18	7	11
Salaries	$13,108	$5,508	$7,600
Clerks—			
Number	8	4	4
Salaries	$3,880	$1,440	$2,440
Wage-earners:			
Total average number	335	155	180
Total wages	$149,114	$69,675	$79,439
Engineers, firemen, and other mechanics—			
Average number	32	11	21
Wages	$18,140	$6,769	$11,371
Quarrymen—			
Average number	149	70	79
Wages	$66,074	$32,028	$34,046
All other wage-earners—			
Average number	154	74	80
Wages	$64,900	$30,878	$34,022
Average number of wage-earners at specified daily rates of pay:			
Engineers—			
$1.25 to $1.49	1	----	1
$1.50 to $1.74	4	1	3
$1.75 to $1.99	1	----	1
$2.00 to $2.24	13	5	8
$2.50 to $2.74	2	2	----
Firemen—			
$1.50 to $1.74	3	----	3
Machinists, blacksmiths, carpenters, and other mechanics—			
$1.50 to $1.74	1	----	1
$1.75 to $1.99	2	1	1
$2.00 to $2.24	4	2	2
$2.50 to $2.74	1	----	1
Quarrymen—			
$0.75 to $0.99	2	2	----
$1.25 to $1.49	73	21	52
$1.50 to $1.74	41	25	16
$1.75 to $1.99	13	12	1
$2.00 to $2.24	20	10	10
All other wage-earners—			
$1.25 to $1.49	57	31	26
$1.50 to $1.74	79	43	36
$1.75 to $1.99	2	----	2
$2.00 to $2.24	16	----	16

	United States.	Ohio.	Pennsylvania.
Average number of wage-earners employed during each month:			
Men 16 years and over—			
January	270	128	142
February	264	122	142
March	335	154	181
April	343	147	196
May	365	169	196
June	341	145	196
July	332	136	196
August	366	170	196
September	380	176	204
October	365	186	179
November	328	162	166
December	331	165	166
Contract work:			
Amount paid	$100	$100	----
Number of employees	2	2	----
Miscellaneous expenses:			
Total	$18,776	$7,566	$11,210
Royalties and rent of quarrying plant	$8,373	$3,139	$5,234
Rent of offices, taxes, insurance, interest, and other sundries	$10,403	$4,427	$5,976
Cost of supplies and materials	$38,386	$13,598	$24,788
Product:			
Total quantity (short tons)	445,903	132,921	312,982
Total value	$421,289	$152,274	$269,015
Glass sand—			
Quantity (short tons)	147,556	20,036	127,520
Value	$130,263	$24,896	$105,367
Engine sand—			
Quantity (short tons)	3,750	3,750	----
Value	$3,000	$3,000	----
Furnace sand—			
Quantity (short tons)	75,637	60,396	15,241
Value	$78,244	$59,348	$18,896
Building sand—			
Quantity (short tons)	31,500	----	31,500
Value	$24,000	----	$24,000
Other uses—			
Quantity (short tons)	187,460	48,739	138,721
Value	$185,782	$65,030	$120,752
Power owned:			
Total horsepower	2,000	805	1,195
Steam—			
Engines—			
Number	33	16	17
Horsepower	1,980	785	1,195
Other power—

CEMENT

CEMENT.

By Story B. Ladd.

Hydraulic cements are of three kinds, Portland or artificial cement, natural-rock cement, and Pozzuolana or slag cement. The last-named class does not fall within the scope of the mining census, nor does the manufacture of any kind of cement, except as it is associated with the mining or quarrying of the raw material; hence the statistics presented in Tables 1 and 8 include only the Portland and natural-rock cement made by establishments mining or quarrying the raw material, at least in part. In cases where the raw material was manufactured into cement by the operator of the mine or quarry, the statistics include the manufacture, as well as the mining and quarrying, of the raw material; and where a part of the raw material was mined or quarried and a part purchased, the complete mining and manufacturing statistics are included, because it was impossible to differentiate the statistics chargeable to the purchased material from those pertaining to material mined or quarried.

The comparative statistics from 1850 to 1902, inclusive, are shown in Table 1.

Table 1.—*Comparative summary: 1850 to 1902.*

	1902	1889	1880	1870[1]	1860[1]	1850[1]

[1] From Census Report on Manufactures.
[2] Not reported.
[3] Establishments.
[4] The United States Geological Survey reports 25,753,504 barrels, valued at $25,366,380, which includes all manufactured cement. The Census reports only the product of operators mining, quarrying, or excavating raw material.
[5] Estimate in Eleventh Census Report on Mining Industries, page xv.

The growth of the industry has been very great. The increase of production in 1889 over 1880 was nearly 240 per cent, and the increase in 1902 over 1889 was more than 250 per cent.

In 1902 there were 93 operators, of whom 4 were individuals, 6 were firms, and 83 were incorporated companies, as shown by Table 8, a detailed summary of the statistics. Of the individual operators, 3 were located in New York and 1 in Minnesota, and of the firms, 4 were in New York and 1 each in Maryland and Minnesota. The 83 corporations, constituting 89.2 per cent of the operators and owning 91 establishments, or 90.1 per cent of the whole, produced 98.3 per cent of the product. All of the Portland cement was made by incorporated companies. The statistics for the present census are the most complete that have ever been published. At the Eleventh Census no statistics in regard to cement production were reported in connection with the mining census, except the estimated quantity and value of the cement product, 7,000,000 barrels, having a total value of $5,000,000.

Capital stock of incorporated companies.—Table 2 presents in detail the capitalization of incorporated companies.

The state of Pennsylvania led both in number of companies and in capital invested, as represented by the par value of stocks and bonds issued, reporting 39.1 per cent of the entire par value. New York, with 13 corporations, ranked second in number of companies, and Michigan was third, with 10 companies. One company operating in Ohio also owns and operates a plant in Indiana; 1 company operating in Indiana also owns and operates a plant in Kentucky; 1 company in Pennsylvania operates 2 plants in that state, and another company in Pennsylvania operates 3 plants in that state and 1 in Indiana. In the case of 1 limestone company in Michigan and 1 in New York, producing cement as a minor product, the capitalization is reported in connection with the limestone industry. Two companies—1 in Alabama and 1 in Michigan—did not report capitalization; the former was an English corporation, and the latter was engaged extensively in other business, cement being but a small part of the total.

TABLE 2.—CAPITALIZATION OF INCORPORATED COMPANIES: 1902.

	United States.	Illinois.	Indiana.	Maryland.	Michigan.	New York.	Ohio.	Pennsylvania.	Virginia.	All other states.

[1] Includes companies distributed as follows: Alabama, 1; California, 2; Colorado, 1; Georgia, 2; Kansas, 2; Kentucky, 1; Missouri, 1; New Jersey, 2; North Dakota, 1; South Dakota, 1; Texas, 2; Utah, 1; West Virginia, 1; Wisconsin, 2.

[2] Includes companies distributed as follows: California, 2; Colorado, 1; Georgia, 2; Kansas, 2; Kentucky, 1; Missouri, 1; New Jersey, 2; North Dakota, 1; South Dakota, 1; Texas, 2; Utah, 1; West Virginia, 1; Wisconsin, 2.

Dividends to the aggregate amount of $1,209,667 were reported as paid by 31 companies, of which 6 were located in New York, 6 in Pennsylvania, 4 in Indiana, 3 in Michigan, 2 each in Illinois, Kansas, Ohio, and New Jersey, and 1 each in Colorado, South Dakota, Utah, and Wisconsin. Dividends to the amount of $251,300 were paid on preferred stock of a total par value of $3,605,000, by 3 companies in Pennsylvania, 2 in New York, and 1 each in Michigan and Ohio; and dividends aggregating $958,367 were paid on common stock of a total par value of $11,441,910, by 4 companies in Indiana, 4 in New York, 3 in Pennsylvania, 2 each in Illinois, Kansas, Michigan, New Jersey and Ohio, and 1 each in Colorado, South Dakota, Utah, and Wisconsin. The dividends paid averaged 7 per cent on the preferred stock and 8.4 per cent on the common stock of the companies reporting them.

The sum of $35,396 was paid in assessments to 2 companies in New York. Outstanding bonds aggregating $8,717,700 were reported by 34 companies; but the interest reported, amounting to $316,962, was paid by only 25 companies on bonds of a par value of $6,081,700, distributed as follows: Pennsylvania, $2,813,000; Michigan, $1,145,800; New York, $787,000; Illinois, $536,500; Virginia, $400,000; Indiana, $185,000; Ohio, $106,000; Maryland, $89,000; and "all other states," $19,400.

Employees and wages.—Of the $7,416,366 paid for salaries and wages, $1,087,514 was paid to 913 salaried officials, clerks, etc., and $6,328,852 to 13,041 wage-earners. The salaried employees comprised 148 general officers, who received $347,132, an average salary of $2,346; 426 superintendents, managers, foremen, surveyors, etc., who received $491,671, an average of $1,154; and 339 clerks, who received $248,711, an average of $734. Of the 13,041 wage-earners 2,092 were engineers, firemen, and other mechanics, who received $1,324,121; 3,251 were miners or quarrymen and miners' helpers, who received $1,440,029; and 111 were boys under 16 years of age, who received $23,499; the 7,587 other wage-earners received $3,541,203.

Mining below ground was reported in the case of 14 mines or quarries, of which 5 were located in New York, 3 in Maryland, and 1 each in Illinois, Indiana, North Dakota, Ohio, Virginia, and Wisconsin. Boys under 16 years of age were employed in 22 mines—6 in Pennsylvania, 5 in New York, 2 each in Kansas and Virginia, and 1 each in Alabama, California, Georgia, Indiana, Maryland, Texas, and Utah. Of these mines, only 1, located in the state of New York, reports the employment of boys underground.

The variation in the numbers of wage-earners employed at different seasons of the year is shown in Table 8, which gives the average number of men and boys employed during each month. Taking the industry as a whole, the minimum number was employed in February and the maximum in September, with a steady increase from February to September, followed by a slight falling off in the fall and early winter. The increase in the number of wage-earners for December over the number employed in January, 35 per cent, reflects the growth of the industry, which was most marked in Michigan, Illinois, and Indiana.

In addition to asking for the average number of employees and the total amount paid as wages, the schedule called for the number of wage-earners employed at specified daily rates of pay. These statistics are shown in the following table:

TABLE 3.—DISTRIBUTION OF WAGE-EARNERS ACCORDING TO DAILY RATES OF PAY, BY OCCUPATIONS: 1902.

RATE PER DAY (DOLLARS).	ALL OCCUPATIONS.		ENGINEERS.		FIREMEN.		MACHINISTS, BLACKSMITHS, CARPENTERS, AND OTHER MECHANICS.		MINERS AND QUARRYMEN.		BOYS UNDER 16 YEARS.		ALL OTHER WAGE-EARNERS.

[1] Less than one-tenth of 1 per cent.

Three-fifths of all wage-earners were paid from $1.25 to $1.74 per day, 29.5 per cent receiving from $1.25 to $1.49, and 31.5 per cent from $1.50 to $1.74; of those at lower rates, 8.4 per cent received from $1 to $1.24 and 2 per cent less than $1; while of those at higher rates 12.5 per cent received from $1.75 to $1.99, and 16.1 per cent $2 and over.

Of the total number of wage-earners 3,031, or 23.2 per cent, were miners or quarrymen; of this class, 2,061, or 68 per cent, received from $1.25 to $1.74 per day. Of the 3,031 miners or quarrymen distributed in Table 3 according to daily rates of pay, there were 449, 14.8 per cent of the total number, for whom rates had to be computed, because they were paid by the ton or cubic yard. The total amount paid them was $215,796.

Contract mining or quarrying was reported for 11 mines or quarries, located 3 each in New York, Ohio, and Pennsylvania, and 1 each in California, Michigan, and Utah, at rates ranging from $0.18 to $0.40 per ton, except in the case of 1 mine in Ohio, where the rate was $1.25 per gross ton. In addition, 1 establishment in Michigan reported the excavation of marl by contract at $0.055 per cubic yard.

Contract work.—Contract work for tunneling, shaft sinking, boring test holes, etc., was reported by 3 establishments, 1 each in Kansas, Kentucky, and New York. The number of men so employed was 34, and the amount paid for such contract work was $10,627.

Supplies, materials, and miscellaneous expenses.—The total expenditure reported for supplies and materials was $9,098,226. As cement is marketed in barrels or bags, the containers constitute quite an item of expense. The total amount reported for miscellaneous expenses was $1,665,520; of this amount, $52,905 was paid by 14 operators—4 in Pennsylvania, 3 in Ohio, and 1 each in Kansas, Maryland, Minnesota, New York, Texas, Utah, and Wisconsin—for royalties and rent of mine or quarry and mining plant, and $1,612,615 was expended for rent of offices, taxes, insurance, interest, and other sundries.

Mechanical power.—The primary power employed in the cement industry aggregated 114,092 horsepower, of which 110,650 was owned and 3,442 rented, the latter being electric power. Of the power owned, 93.8 per cent was steampower. Electric motors were employed in the industry of a total capacity of 17,420 horsepower.

Production.—The total production of hydraulic cement by establishments mining or quarrying raw material in whole or in part, was 24,655,360 barrels, valued at $24,268,338. Pennsylvania was the largest producer, reporting 9,360,802 barrels, or 38 per cent of the entire product; this state and New York together reported 57.2 per cent of the total production. Pennsylvania produced 51.3 per cent of the Portland cement, and New York 44.9 per cent of the natural-rock cement.

Of the 101 mines or quarries covered by Tables 1 and 8, 54 manufactured Portland cement only and 37 natural-rock cement only, while 10 produced both Portland and natural-rock cement. The 54 establishments manufacturing only Portland cement produced 14,115,121 barrels, at an aggregate expense of $12,655,189; nearly 90 per cent of this product was reported by 40 establishments in the states of Illinois, Indiana, Michigan, New Jersey, New York, Ohio, and Pennsylvania. Among the 54 mines or quarries producing Portland cement exclusively there were 13—7 in Michigan, 3 in New York, 2 in Ohio, and 1 in Indiana—which reported the manufacture, in the aggregate, of 1,981,415 barrels of Portland cement from marl. The marl mined or excavated by these establishments was reported in some

cases in cubic yards and in other cases in tons, the quantity reported being 723,385 cubic yards and 359,277 tons. In Michigan the development of the marl cement industry has been very great; the 7 establishments reporting from that state excavated 655,902 cubic yards and 20,000 tons of marl, and produced 1,167,052 barrels of cement.

The 37 establishments manufacturing only natural-rock cement produced, in the aggregate, 6,954,704 barrels of cement at an aggregate expense of $2,732,514.

The entire hydraulic cement production of the United States for 1902, including cement manufactured by companies not mining or quarrying any portion of the material, is shown in Table 4.

TABLE 4.—CEMENT PRODUCTION: 1902.

CEMENT MANUFACTURED BY—	Number of establishments.	Number of operators.	PRODUCTION. Total. Barrels.	Total. Value.	Portland cement. Barrels.	Portland cement. Value.	Natural-rock cement. Barrels.	Natural-rock cement. Value.	Pozzuolana or slag cement. Barrels.	Pozzuolana or slag cement. Value.
All establishments	112	102	25,753,504	$25,366,380	17,230,644	$20,864,078	8,044,305	$4,076,630	478,555	$425,672
Establishments mining or quarrying raw material in whole or in part	101	93	24,655,360	24,268,338	16,691,055	20,231,708	7,964,305	4,036,630	.....	.....
Establishments not mining or quarrying raw material[1]	11	9	1,098,144	1,098,042	539,589	632,370	80,000	40,000	478,555	425,672

[1] Not included in mining census reports, but included in "Mineral Resources of the United States," published by the United States Geological Survey.

Of the 25,753,504 barrels of hydraulic cement of all kinds manufactured in 1902, 66.9 per cent was Portland cement, 31.2 per cent was natural-rock cement, and 1.9 per cent was Pozzuolana, or slag cement. Of the entire production, 24,655,360 barrels, or 95.7 per cent, was the product of establishments that mined or quarried raw material, at least in part; this product included 96.9 per cent of all Portland cement and 99 per cent of all the natural-rock cement manufactured, but none of the Pozzuolana or slag cement. Cement was manufactured from purchased material by 11 establishments. Of these, 4 establishments—1 each in Colorado, Illinois, Ohio, and Pennsylvania—manufactured Portland cement; 1 establishment in Kansas manufactured natural-rock cement; and 6 establishments—2 in Alabama and 1 each in Illinois, Maryland, New Jersey, and Ohio—made Pozzuolana, or slag cement. The 2 establishments in Alabama manufacturing slag cement were owned by the same company, and 1 company in Illinois manufactured both Portland and slag cement.

The growth of the entire cement industry from 1890 to 1902, inclusive, and the imports during the same period are shown in the following table:

TABLE 5.—CEMENT PRODUCTION AND IMPORTS: 1890 TO 1902.

[Compiled from reports of United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	PRODUCTION. Total. Barrels.	Total. Value.	Portland cement. Barrels.	Portland cement. Value.	Natural rock cement. Barrels.	Natural rock cement. Value.	Pozzuolana, or slag cement. Barrels.	Pozzuolana, or slag cement. Value.	Imports (barrels).

[1] Not including 233,000 barrels of Pozzuolana, or slag cement, the value of which was not reported.
[2] Not reported.
[3] Includes cement manufactured by the 11 establishments not mining or quarrying any raw material, and therefore not included in mining census reports. (See Table 4.)

The production of cement has steadily increased throughout the period covered by this table, except in 1892–93. The natural-rock cement production, however, shows no real growth; it reached its maximum in 1899, and the production in 1902, though greater than that in 1901, is less than that in 1892. On the other hand, the growth in the production of Portland cement has been very great; from 1892 to 1902 the rate of yearly growth averaged 40 per cent, ranging from 7.9 per cent in 1892–93 to 73.5 per cent in 1896–97, so that

during the decade the output increased more than thirty-fold. Portland cement outstripped natural rock cement in value in 1897, and in quantity in 1900. The imports reached a maximum in 1895; since that year there has been, on the whole, a considerable decrease, the imports for 1902 exceeding very slightly those for 1890. Since 1897, except in 1900, the annual imports have been below the average of the imports for the entire period of thirteen years, and in 1902 they were approximately on a par with the imports for 1890.

Kilns.—The kiln equipment of the 101 establishments included in Table 8 comprised 584 vertical and 451 rotary kilns. As a rule, natural cement rock is calcined in vertical and Portland cement mixtures in rotary kilns; but 3 establishments in New York and 1 in South Dakota reported the use of 47 vertical kilns in the manufacture of Portland cement, and 1 establishment in Minnesota used 5 rotary kilns for natural-rock cement.

Nonproducers.—There were 51 nonproducing cement establishments, of which 20 were new plants in course of erection. The number, distribution, and character of ownership of these establishments are shown in the following table:

TABLE 6.—*Nonproducing mines or quarries: 1902.*

	United States.	Indiana.	Michigan.	New Jersey.	New York.	Ohio.	Pennsylvania.	Virginia.	All other states and territories.[1]
Number of mines or quarries	51	[2]10	9	3	6	3	5	3	12
New mines or quarries	20	.....	8	2	1	1	4	.....	[3]4
Number of operators	49	9	9	3	6	3	5	[4]2	12

[1] Includes 1 mine or quarry each in Arkansas, California, Colorado, Florida, Georgia, Illinois, Kentucky, Massachusetts, Nebraska, New Mexico, Texas, and West Virginia.
[2] One owned by an active establishment operating in Kentucky.
[3] Includes 1 mine or quarry each in Arkansas, California, Georgia, and New Mexico.
[4] One individual owns 2 idle mines or quarries.

Of the 51 nonproducing establishments, 31—10 in Indiana, 5 in New York, 3 in Virginia, 2 in Ohio, and 1 each in Colorado, Florida, Illinois, Kentucky, Massachusetts, Michigan, Nebraska, New Jersey, Pennsylvania, Texas, and West Virginia—were properly "idle establishments." The other 20—8 in Michigan, 4 in Pennsylvania, 2 in New Jersey, and 1 each in Arkansas, California, Georgia, New Mexico, New York, and Ohio—were in course of erection during the year.

There were 44 incorporated companies which reported ownership of nonproducing mines or quarries—24 owning idle establishments and 20 owning the 20 establishments in course of construction. Capitalization was reported by 16 of these companies, distributed as follows: Companies owning idle establishments, 6 in Indiana and 1 each in Michigan, New York, and Ohio, or a total of 9; companies owning establishments in course of construction (or "new establishments"), 3 in Michigan and 1 each in Arkansas, New Jersey, New York, and Pennsylvania, or a total of 7. The statistics of the capitalization of the nonproducing companies reporting capitalization are shown in Table 7.

TABLE 7.—*Capitalization of nonproducing incorporated companies: 1902.*

	Total.	Idle companies.	New companies owning plants in course of construction.
Number of incorporated companies	44	24	20

If the 7 new companies reporting capitalization are representative of all such companies, there has been a marked increase in the average capitalization per company. The 7 new companies reporting capitalization show a total par value of stocks and bonds issued amounting to $15,191,000, or an average of $2,170,143, as compared with an average of $670,480 for the 83 active companies for which capitalization is reported in Table 2.

The following statistics were reported by 9 of the 51 nonproducing mines or quarries—5 in Indiana and 1 each in New Jersey, New York, Michigan, and Pennsylvania:

Summary, nonproducing mines or quarries: 1902.

Number of mines or quarries reporting	9
Salaried officials, clerks, etc.:	
Number	43
Salaries	$52,333
Wage-earners:	
Average number	340
Wages	$214,617
Miscellaneous expenses	$36,647
Cost of supplies and materials	$3,086
Total horsepower	11,187

Of the salaries, $14,380 was paid to 9 general officers; $28,513 to 16 superintendents, managers, foremen, surveyors, etc.; and $9,440 to 18 clerks. Of the wages, $155,849 was paid to 229 engineers, firemen, and other mechanics; $17,458 to 28 miners or quarrymen—26 above ground and 2 below ground—and $41,310 to 83 other wage-earners. The miscellaneous expenses repre-

sented the rent of offices, taxes, insurance, interest, and other sundries. The mechanical power was furnished by 26 steam engines, of 8,835 horsepower; 2 gas or gasoline engines, of 12 horsepower; 1 water wheel of 40 horsepower; and 78 electric motors, of 2,300 horsepower.

A detailed summary showing the statistics for cement during 1902 is given in Table 8.

DESCRIPTIVE.

Hydraulic cements are of three general classes:[1]

(1) Portland cement, a compound consisting essentially of lime, silica, and alumina, produced by mixing intimately some form of calcium carbonate with the necessary proportion of clay, calcining the mixture at a high heat, and grinding the resulting clinker to a fine powder. A mixture of Portland cement and sand ground to an extremely fine powder is called sand cement.

(2) Natural-rock cement, produced by calcining at a comparatively low heat a natural product—such as argillaceous limestone—possessing in its composition lime and clay in proportions adapted to form a hydraulic cement, and usually containing also a considerable proportion of magnesia.

(3) Pozzuolana, or slag cement, produced by mixing with slacked lime a natural volcanic scoria or granulated blast furnace slag of suitable composition.

The chemical constituents of the three general classes of hydraulic cement are approximately as follows:

CONSTITUENTS.	Portland.	Natural rock.	Slag.
Lime (per cent)	58.0 to 67.0	32.3 to 53.5	36.0 to 55.0
Silica (per cent)	20.3 to 26.1	21.1 to 35.4	18.0 to 28.0
Alumina (per cent)	5.2 to 10.6	6.3 to 14.5	9.0 to 19.0
Iron oxide (per cent)	2.1 to 5.3	1.7 to 5.1	0.3 to 2.8
Magnesia (per cent)	0.3 to 2.3	1.4 to 20.9	0.5 to 7.0
Sulphuric acid (per cent)	0.3 to 1.8	.....	0.2 to 2.7

The process of formation and hardening of the cement is similar in all cases, depending chiefly upon the formation of calcium silicates, which become hydrated and crystallize under the action of water. If it were possible to find a natural product containing lime and clay in the right proportions, a cement of the correct Portland standard could be made from it by the simple operations of calcining and grinding; but a variation of 1 per cent from the correct standard greatly reduces the value of the cement. Most of the argillaceous limestones of the United States contain a high proportion of magnesia and an excess of clay. If burned at the high temperature necessary to produce Portland cement, they fuse to a slag which does not possess hydraulic properties; but when burned at a heat only sufficient to drive off the carbonic acid, they yield a soft yellow clinker, which, when ground, gives the natural-rock cement of commerce.

[1] "Portland Cement," by S. B. Newberry, in "The Cement Industry," reprinted from the Engineering Record, has been largely drawn from.

PORTLAND CEMENT.

Ingredients used.—The necessary materials for Portland cement are calcium carbonate (usually in the form of limestone, chalk, or marl) and clay or shale. The relative proportions of the two depend upon their varying composition.

The calcium carbonate should be as pure as possible, except for the presence of clay. Magnesia is always present to some extent, and though it is generally agreed that up to 3.5 per cent it is harmless, a large percentage is objectionable. Calcium sulphate in excess of about 2.5 per cent is also objectionable, unless a decided oxidizing flame be maintained in burning, as it is liable to be reduced to the sulphide. Both magnesia and calcium sulphate are considered especially objectionable in cements that are to be exposed to the action of sea water.

In England a comparatively soft chalk is generally used; in Germany, chalk or limestone. In the United States a large part of the Portland cement is made from the slate-like limestone of the Lehigh valley region. This material contains rather more clay than is required for a correct mixture, so that a small proportion of pure limestone—usually from 10 to 20 per cent—is added. In New York, Ohio, and Michigan marl, a soft fresh-water deposit similar to chalk, is generally employed. Pure limestone is used in a few cases only.

The chemical composition of certain typical forms of calcium carbonate used in the manufacture of Portland cement is shown in the following table:

CONSTITUENTS.	CHALK.	CEMENT ROCK.			MARL.	
	England (Reed).	Lasalle, Ill.	Phillipsburg, N. J.	Siegfried, Pa.	Sandusky, Ohio.	Syracuse, Ind.
Calcium carbonate	98.57	88.16	70.10	68.91	91.77	88.49
Silica	0.64	8.20	15.05	17.32	0.22	1.78
Alumina	0.16	1.00	9.02	7.07	1.22	0.91
Iron oxide	0.08	0.30	1.27	2.04	0.40	0.30
Magnesium carbonate	0.38	1.78	3.96	4.28	0.53	2.71
Calcium sulphate	.....	.....	.....	.....	3.19	1.58

The clay should be highly siliceous, low in magnesia and sulphates, and free from sand. For the best results the proportion of silica should be at least three times as great as that of iron oxide and alumina combined. Highly aluminous clays give a fusible clinker and quick-setting cement, while clays containing more than 5 per cent of iron oxide give a dark-colored cement.

The following table presents an analysis of a few typical clays used in Portland cement manufacture:

CONSTITUENTS.	Medway, England.	Harper, Ohio.	Sandusky, Ohio.	Lasalle, Ill.
Silica	70.56	51.50	65.41	54.30
Alumina	14.52	13.23	16.54	19.33
Iron oxide	3.06	3.30	6.06	5.57
Lime	4.43	11.52	2.22	3.29
Magnesia	.....	3.45	1.88	2.57
Carbonic acid	3.48	12.85	.....	.....
Alkalies	3.95	.....	.....	.....

The small proportion of alkalies present in ordinary clays exerts but little influence and hence is not generally determined.

Mixing.—The method of mixing originally practiced in England was the wet process, in which the materials were ground and mixed in water, and settled in reservoirs, and the "slurry" dried previous to burning. In the dry process, now largely used, the materials are ground and mixed in the dry state. Marl and clay are mixed in a plastic condition. Rock crushers, followed by buhrstones, emery mills, tube mills, or Griffin mills, are generally used for the dry grinding of raw material, and pans with edge runners, followed by tube mills, for wet grinding. The chemical composition of the mixture is constantly tested, and the percentage of calcium carbonate is kept within the 0.5 per cent of that found to be correct for the materials used.

Burning.—Over 95 per cent of the Portland cement is now burned in rotary kilns. The rotary kiln consists of a slightly inclined cylinder, lined with fire brick, turning at the rate of one revolution in from one to three minutes. Fuel oil was formerly used as a source of heat, but powdered coal is now generally employed. The cement material is fed in continuously at the upper end in the form of dry powder, or, in the case of marl and clay, as liquid mud. Descending gradually, it parts with its water, if any, in the upper third of the kiln, becomes heated to redness, loses its carbonic acid, forms small rounded balls which reach a nearly white heat in the lower third of the kiln, and finally issues at the lower end as well-burned black clinker in grains about pea size.

When the burning is done in vertical kilns, the dry powder is first moistened and molded into bricks, which are again dried before being fed into the kiln. According to Le Chatelier, the following changes take place during the burning: At a red heat the combined water is expelled from the clay; at a somewhat higher temperature the calcium carbonate is decomposed into carbonic acid gas, which escapes, and lime, which immediately enters into combination with the silica and alumina of the clay, producing calcium silicates and aluminates. At first, fusible glasses, rich in silica, are formed; by combining with more lime, these gradually become more and more basic, until at last the tricalcium silicate is produced. The iron and alumina also remain in combination with lime as an alumino-ferrite.

The proper degree of burning is indicated by the formation of a dense green-black clinker. Underburned clinker is brownish and soft, while overburned clinker is fused and slag-like; long-continued burning or an excess of clay causes the clinker to "dust" or fall to powder on cooling, the resulting powder showing little or no hydraulic properties. Underburned cement is apt to be quick-setting and to expand and crack in hardening; on the other hand, overburned cement is usually slow in setting and hardening, though it may show excellent tests at long periods. Cement properly proportioned, mixed, and burned does not begin to set in less than two hours after mixing with water, but after the setting begins it hardens rapidly and shows a steady gain in strength, especially when tested with sand, up to several years. It is an almost universal practice to add from 1 to 2 per cent of ground gypsum to retard the setting.

Grinding.—Portland cement clinker was formerly ground with buhrstones and bolted through revolving screens. At present the Griffin mill or the German ball mill, followed by the tube mill, is generally used. A degree of fineness, such that 92 to 93 per cent will pass through a No. 100 sieve, is generally attained. Finer grinding can easily be accomplished, if necessary, but is rarely demanded. There is, of course, a point beyond which it is not economical to carry the fine pulverizing of cement, since the same result can be accomplished by using slightly richer mixtures.

The numerous tests shown in the reports of Government and private engineers warrant the claim that no Portland cement made in any foreign country equals the product of the leading American factories.

NATURAL ROCK CEMENT.

Of the natural rock cement produced in the United States in 1902, about 45 per cent came from the state of New York; about 22 per cent from Kentucky and Indiana, within a radius of 15 miles of Louisville, Ky.; and the remainder largely from Pennsylvania and Illinois.

Rosendale cements.—Of the natural-rock cements the Rosendale cements, manufactured in Ulster county, N. Y., from a natural cement rock known as the Tentaculite or water-lime deposit of the lower Helderberg group of the New York Geological Survey, are typical.

The Rosendale cement industry is the oldest manufacture of hydraulic cement in the country. Dating from 1832, the industry has been developed conservatively and successfully.

The rock deposit is a magnesian limestone, of which two different beds, known respectively as the "light" rock and the "dark" rock, are quarried for cement. Both rocks are hard, compact, and close-grained, the light rock having a steely-blue color, and the dark a duller and deader color and a more shaly appearance. Apparently the light rock contains the more lime and the dark the more clay. After calcination the light rock is yellow, and the dark a redder or dark sienna color. It is a tradition that no good cement can be made without a mixture of the two.

At Binnewater, Ulster county, the depth of the dark-rock deposit, which is the lower bed of cement rock, is about 18 feet, that of the light rock is from 10 to 17 feet, and that of the unworked strata between the two is about 12 feet. The dip varies, but is generally about 45 degrees. The general mining scheme is to run slopes

to a depth of about 40 feet, following the dip of the dark rock, and then to start breasts or headings in both directions along the strike. When the headings have been run out to daylight, to property limits, or to the limit of economical working, the slope is run down 40 or 50 feet farther and new headings started. The rock is loaded on cars which are run through the headings to the foot of the slope and hauled up by cable. To get at the light-rock deposit, which is overhead, horizontal gangways are cut from the gangways in the dark rock through the hanging wall into the bed of light rock, and headings are then started in it in both directions, just as in the lower formation, the cars being run through the connecting gangways and up the slope.

In chemical composition the Rosendale cements are remarkable for the high proportion of magnesia they contain; it varies considerably in different Rosendale brands, but the following analysis is typical of these cements as a class:[1]

Silica	24.30
Alumina	7.22
Ferric oxide	5.06
Lime	33.70
Magnesia	20.94
Volatile matter and undetermined	8.78
Total	100.00

The condition of the successful use of magnesian limestones is light burning, and this requirement is carefully observed in all the Rosendale factories.

Louisville cements.—The so-called Louisville cements are next in importance to the Rosendale product. An extensive deposit of limestone occurs at Louisville, Ky., forming the bed of the Ohio river, and causing the falls and rapids at that place. The first manufacture of Louisville cement began alongside of and in conjunction with the construction of the Louisville and Portland Canal around the Louisville falls. The largest plant in the Louisville district is at Speeds, Indiana.

The cement rock is of the same geological horizon as the water-lime deposits of New York, Pennsylvania, and Wisconsin. A general analysis is about as follows:

Silica and insoluble matter	15.0
Alumina and iron oxide	6.0
Calcium carbonate	61.0
Calcium sulphate	5.0
Magnesium carbonate	10.0
Water, alkalies, etc	3.0
Total	100.0

It is worked both in open quarries and by mining. At the Speeds mills the rock is graded into three sizes, at a breaker provided with screens, the fine stuff calcining more readily than heavy rock.

Manufacturing process.—For calcining natural cement rock, vertical kilns are generally used. They are operated continuously, by drawing from the bottom and charging at the top. In charging, a layer of rock is thrown in, then a thin layer of anthracite pea coal, then another layer of rock, etc. The fuel consumption is low, the output of cement per ton of coal being quite high. At Binnewater the kilns are 28 feet high and 10 feet in diameter, with a daily capacity of from 90 to 100 barrels of marketable cement stone, after discarding all hard-burned clinker and sorting out the underburned clinker for recalcination. At the Speeds mills they are 30 feet high and have an inside diameter of 13 feet, with a daily capacity up to 250 barrels.

The calcined rock is run through crackers and then screened; the coarse rock is next ground in mills, but the finest grades pass directly to the barrel packers. The product is packed as it is ground—nearly all of it in barrels.

[1] The Cement Industry, page 153.

SLAG CEMENT.

The manufacture of hydraulic cement from furnace slag has reached considerable proportions abroad, but in this country it is comparatively a new industry. It is not directly within the scope of the mining census, but it is noticed briefly because it utilizes a waste product of mined material.

It is only occasionally that ores and fluxes employed in blast furnaces will produce slag suitable for cement, furnace slags as ordinarily produced by casting and slow cooling being devoid of hydraulic properties. Slag to be used for cement is run off from the furnaces and dropped in a molten state into a trough through which is forced a large stream of cold water; the slag solidifies in vesicles or bubbles, which break up into thin, shell-like pieces. The best grade of such slag has a delicate blue color, and though hard is thin and porous, and hence is readily crushed. The rest of the process is extremely simple, consisting in drying the slag, mixing it with the proper proportions of slaked lime, and then grinding the mixture to a fine powder. The Maryland Cement Company utilizes the slag from the blast furnaces of the Maryland Steel Company, at Sparrow Point, Md. Cuban iron ores are largely used in these furnaces with oyster shells as flux.

INVENTIONS.

Invention has played an important part in the development of the cement industry, both in the improvement of cement compositions and processes of manufacture and in the perfecting of methods and machinery, whereby the cost of manufacture has been greatly reduced and uniformity of product secured. Many of the operators own and control patents for such inventions; a digest of all patents pertaining to processes or compositions employed in the industry—not including patents for apparatus or machines—is attached hereto. The term of a United States patent is seventeen years, so that all patents which have run for that period are public property.

APPENDIX.

DIGEST OF UNITED STATES PATENTS RELATING TO CEMENT.[1]

371—October 6, 1837. E. C. WARNER. *Mode of manufacturing hydraulic cement from basanite.*

Basanite Lydian stone, sometimes called "touchstone," is calcined to a red heat and ground.

119413—September 26, 1871. D. C. SAYLOR. *Improvement in the manufacture of cement.*

A hydraulic cement is produced from argillo-magnesian and argillo-calcareous limestone.

126989—May 21, 1872. D. C. SAYLOR. *Improvement in the manufacture of hydraulic cement.*

Argillo-magnesian limestone is burned and crushed, one-fifth of its weight of raw stone is added thereto, and the mass is then ground.

154641—September 1, 1874. F. E. and W. L. BROWN. *Improvement in hydraulic cement.*

Coralline, coral rock, or fossil coral is used for the manufacture of hydraulic cement.

167653—September 14, 1875. C. F. DUNDERDALE. *Improvement in hydraulic cement.*

Kaolin, or other silicate of aluminum, fuller's earth, and lime are mixed, burned, and ground.

174387—March 7, 1876. A. SMITH. *Method of manufacturing lime and cement.*

Lime, or cement rock, is burned with oil, delivered into the combustion chamber in a fluid state, in spray, or as vapor, along with steam, superheated or not, and air.

176938—May 2, 1876. C. F. DUNDERDALE. *Improvement in the manufacture of artificial hydraulic cement.*

The cement materials are crushed and mixed in water in a dense, semifluid state, flowed direct onto a drying floor or pan, then pressed and burned.

195749—October 2, 1877. C. F. DUNDERDALE. *Improvement in compositions for making hydraulic cement.*

It consists of infusorial silica and a silicate of aluminum with lime, burned and ground.

204532—June 18, 1878. W. J. BUDINGTON. *Improvement in the manufacture of hydraulic cement.*

A cement made of fossiliferous limestone and blue clay.

205253—June 25, 1878. J. DIMELOW. *Improvement in the manufacture of hydraulic cement.*

A hydraulic cement formed of rotten, decomposed, or refuse limestone or marble, and the deposit of rivers, in about equal proportions.

205616—July 2, 1878. U. CUMMINGS and L. J. BENNETT. *Improvement in the manufacture of hydraulic cement.*

The method consists in first crushing and disintegrating the calcined and the vitrified portions of the cement stone, then separating the vitrified portion by screening or bolting and reducing the vitrified portion separately to powder.

212094—February 11, 1879. J. A. FRANCIS. *Improvement in the manufacture of hydraulic cement.*

It consists in the use of blue clay combined with coal ashes and sewer mud.

213459—March 18, 1879. C. H. SLICER. *Manufacture of Portland cement.*

The cement making material consists of ground oyster shells, raw or burned, mixed with siliceous clay.

217415—July 8, 1879. J. K. SHINN. *Manufacture of lime and cement.*

To rapidly produce lime and cement, the raw material is subjected, while burning, to the action of a forced blast, continued until burning is complete, and the forced blast is then sustained to effect rapid cooling.

222004—November 25, 1879. C. BROWN. *Improvement in the manufacture of artificial hydraulic or Portland cement.*

The mixed raw material is molded into hollow cylindrical forms or perforated sphere balls.

223815—January 27, 1880. F. RANSOME. *Manufacture of cement and artificial stone.*

A white or artificially tinted cement is made from a mixture of kaolin or china clay and chalk or marble, by burning in muffle-kilns or retorts without contact with fuel.

230865—August 10, 1880. A. T. EASTERBY. *Hydraulic cement.*

Travertine is employed for the manufacture of hydraulic cement.

231172—August 17, 1880. H. JORDAN. *Cement compound.*

A cement compound, to be calcined, composed of silica, oxide of iron, and alumina, combined with the refuse from soda works, composed of lime, soda, potash, magnesia, and alum, tempered with refuse from gas works or tanneries.

231858—August 31, 1880. E. SOLVAY. *Process for the manufacture of cement.*

The residue from the decomposition of calcium chloride by a silicate of aluminum, such as clay, is used as the basis for the manufacture of cement.

237500—February 8, 1881. J. DIMELOW and R. M. PEADRO. *Manufacture of hydraulic cement and lime.*

Rotten or decomposed limestone is burned and then subjected to currents of air or steam in a tightly closed receptacle, and the material then sifted, with or without grinding.

245574—August 9, 1881. J. B. SPEED. *Treatment of hydraulic cement in the kiln.*

Steam is admitted to the mass after it has fallen below the point where it is burned.

245699—August 16, 1881. W. J. BUDINGTON. *Manufacture of hydraulic cement.*

It is made of white marble of the second formation and blue clay.

[1] Printed copies of patents are sold by the Commissioner of Patents at 5 cents each.

249548—November 15, 1881. J. Reese. *Preparing, indurating, and solidifying calcareous lining materials for furnaces.*

Lime is mixed with carbon or a hydrocarbon, then subjected to a high temperature in a cupola until fusion takes place, and, finally, run into suitable shapes for linings.

256103—April 4, 1882. V. Einaigl. *Manufacture of artificial stone.*

A mixture of carbonate of sodium, carbonate of potassium, calcined quartz sand, oxide of calcium, oxide of magnesium, clay, and siliceous sand forms an artificial stone. A hydraulic cement is produced without calcination by adding to 120 parts of said mixture 300 parts of carbonate of lime, 200 parts of oxide of calcium, of which 150 parts are previously slaked, and 380 parts of brick-dust.

260546—July 4, 1882. E. J. De Smedt. *Manufacture of hydraulic lime and hydraulic cement.*

The lime of cement stone is treated, at the time of calcination or afterwards, to a red heat while in contact with carbonic acid.

263310—August 29, 1882. W. F. Browne. *Process of and means for manufacturing a heating fuel for burning lime, etc.*

The products of combustion are exhausted from a lime kiln, and forced by a jet of gaseous vapor under pressure into a carbureting chamber, where the mixture is enriched with oil vapor; it is then forced under pressure into the kiln, whereby the hot products of combustion and gases are circulated through the latter, thus insuring uniform burning.

263873—September 5, 1882. E. J. De Smedt. *Manufacture of hydraulic cement.*

Slow-setting hydraulic cement is produced from cement stone containing an excess of free anhydrous lime, by adding to the calcined stone, before or after grinding, sufficient water to combine with the free anhydrous lime, forming calcium hydrate.

270097—January 2, 1883. J. Murphy. *Hydraulic cement.*

It is composed of iron slag, soapstone, and burned or roasted clay and lime, in the proportions of 2 parts of slag to 1 part of each of the other ingredients.

270608—January 16, 1883. L. Roth. *Manufacture of cement.*

A cement is formed by calcining and grinding a mixture of bauxite, or minerals similar to bauxite, with quartz, hydrated silicic acid, infusorial earth, blast-furnace slag or other silicates, and lime, either as limestone, chalk, or burnt lime, with or without admixture of dolomite, oxide of iron, raw soda, alkali ash, or other fluxes.

274288—March 20, 1883. E. J. De Smedt. *Art of manufacturing Portland cement.*

A hydrocarbon or other combustible is added to and mixed with the cement material prior to calcining.

274734—March 27, 1883. E. J. De Smedt. *Manufacture of Portland cement.*

Enough lime is combined with cement rock or hydraulic limestone, either before or after calcining, to bring the percentage of lime up to about 70 per cent.

274735—March 27, 1883. E. J. De Smedt. *Manufacture of Portland cement.*

Enough dolomite is combined with cement rocks or hydraulic limestone, either before or after calcining, to bring the percentage of lime and magnesia up to about 70 per cent.

275369—April 10, 1883. E. J. De Smedt. *Hydraulic cement compound.*

A cold, slow-setting hydraulic cement, composed of not more than 50 per cent in bulk of a slaty or siliceous non-cement producing rock in combination with not less than 50 per cent of the hot, quick-setting cement rock in common use for cement manufacture.

279354—June 12, 1883. E. J. De Smedt. *Art of manufacturing Portland cement.*

Natural rock is calcined, ground, formed into a cement paste, and then recalcined and reground.

281965—July 24, 1883. W. J. Budington. *Cement compound.*

It is composed of the variegated marble of the second formation (dark and white), and blue clay.

287941—November 6, 1883. W. Jones. *Hydraulic Portland cement.*

Hydraulic Portland cement is made from argillaceous limestone or dolomite containing an excess of clay, by mixing therewith lime or its carbonate in such quantity that the mixture shall contain 70 to 80 per cent of carbonate of lime, then molding, calcining, and grinding.

292329—January 22, 1884. R. W. Lesley and J. M. Willcox. *Manufacture of Portland cement.*

The pulverized cement material is dampened slightly so that it is still a powder and not a paste, molded into balls or lumps by hard pressure, and then calcined and ground.

294080—February 26, 1884. L. Roth. *Manufacture of cement.*

A mixture of blast-furnace cinder, say 100 pounds; carbonate of lime, 135 pounds; and an alkaline chloride, such as carnallite, 15 to 20 pounds in a saturated solution, is calcined and ground.

300790—June 24, 1884. J. Murphy. *Hydraulic cement.*

It is composed of fibrolite, margarite, iron slag, shell marl, and clay, mixed, burned, and ground.

305201—September 16, 1884. R. W. Lesley. *Manufacture of Portland cement.*

Lime, or lime and magnesia in any of their forms, and slate are mixed in substantially such proportions as to make the manufactured cement analyze about 70 per cent of lime, or lime and magnesia, to 30 per cent of alumina and silica, then calcined and ground.

305753—September 30, 1884. R. W. Lesley. *Manufacture of hydraulic cement.*

A slow-setting hydraulic cement is made by mixing ferruginous earths or stones, such as are used in the manufacture of the mineral brown and red paints of commerce, with quick-setting cement rocks in suitable proportions, and then calcining and grinding.

305754—September 30, 1884. R. W. Lesley and D. Griffiths. *Manufacture of Portland cement.*

Iron slag or cinder, as an essential ingredient, is mixed with lime, or lime and magnesia in any of their forms, and calcined and ground, the proportions being such as to bring the percentage of lime, or lime and magnesia, up to about 70 per cent.

305970—September 30, 1884. S. H. Short. *Manufacture of hydraulic cement.*

A mixture of limestone containing from 5 to 15 per cent of clay and from 3 to 10 per cent of magnesia, mixed with a clay containing about 60 per cent of carbonate of lime, 30 per cent of silica, and 10 per cent of magnesia and alkaline carbonates, is formed into bricks, burned, and ground.

309150—December 9, 1884. E. F. Loiseau. *Art of manufacturing Portland cement.*

The cement powder is kept in a granular condition before it goes upon the rolls, by the addition of "binders" of larger size than the cement powder, and composed preferably of coke dust, coal, culm, raw cement, or limestone.

309270—December 16, 1884. S. T. Wellman and G. W. Goetz. *Plant for and process of making lime.*

The process or mode of expelling or driving off carbonic acid gas by driving or drawing through the limestone air which has been more or less highly heated.

311895—February 10, 1885. D. Griffiths. *Manufacture of hydraulic cement.*

Raw rocks containing silica, preferably slates or argillo-calcareous limestones, and slaked lime, are incorporated with calcined cement rock or hydraulic limestone of the kind that produces hot, quick-setting cement.

313217—March 3, 1885. R. W. Lesley. *Manufacture of Portland cement.*

Black or dark-colored cement is produced by incorporating black chalk with the cement material after calcination.

315711—April 14, 1885. R. Bryce. *Manufacture of hydraulic cement.*

Leitchfield marl or shale, say 5 parts, and limestone 11 parts, are ground together, compressed into bricks, calcined, and ground.

321120—June 30, 1885. R. W. Lesley and D. Griffiths. *Art of manufacturing Portland cement.*

To destroy the clinker bridge formed in a kiln during the operation of calcining cement making material to a clinker, a current of cold air is directed against the underface of said bridge to effect the cooling, contraction, and breaking down of the same.

321121—June 30, 1885. R. W. Lesley and D. Griffiths. *Manufacture of cement.*

Cement is artificially seasoned after grinding by submitting it to the action of a forced current of air charged with moisture.

321589—July 7, 1885. J. Dimelow. *Manufacture of hydraulic cement.*

Decomposed limestone is employed for the manufacture of cement.

330602—November 17, 1885. H. Mathey. *Manufacture of cement.*

Cement rock is ground to a fine powder, which is then calcined.

331243—November 24, 1885. W. Joy. *Manufacture of cement.*

Wet slurry or a mixture of wet slurry and fuel is charged into a cement kiln, in successive portions, on the burning charge, at the parts where the charge is burning most freely.

333370—December 29, 1885. J. M. Willcox. *Manufacture of Portland cement.*

Powdered cement making material is mixed with a binding medium, which will be made soft and fluid by heat and which will harden when cooled—such as pitch—and molded and calcined, the binder finally volatilizing in the furnace.

339673—April 13, 1886. H. Mathey. *Manufacture of cement.*

Crushed rock is calcined in a revolving cylinder, and then pulverized.

340357—April 20, 1886. F. Ransome. *Manufacturing cement, etc.*

The cement material, reduced to a powder, is burned in a revolving furnace while exposed to the flame of producer gas mixed with a suitable amount of oxygen.

342784—June 1, 1886. U. Cummings. *Manufacture of cement.*

The cement making material consists of about 1,266 parts of gypsum by weight and of 400 parts of clay.

343182—June 8, 1886. H. Mathey. *Manufacture of hydraulic cement.*

The process consists in pulverizing natural cement rock, adding alluvial clay, mixing, and finally burning under agitation.

343183—June 8, 1886. H. Mathey. *Manufacture of hydraulic cement.*

Cement is colored by adding a metallic oxide to the burned cement rock before final pulverization.

343184—June 8, 1886. H. Mathey. *Manufacture of hydraulic cement.*

A pulverized metallic ore roasted to an oxide is added to the roasted cement of No. 343182 and the mixture ground.

343913—June 15, 1886. H. C. and D. Millen. *Process of manufacturing hydraulic cement.*

Fresh broken clay and marl are piled in alternate layers and allowed to remain until the clay absorbs the surplus moisture of the marl, when the mass is removed in vertical slices, reduced to a plastic condition, cut into blocks, dried, calcined, and ground.

346525—August 3, 1886. J. Anderson. *Making hydraulic cement.*

Crushed cement or limestone rock is immersed in a solution of acetic acid of moderate strength for about three hours, and then calcined, Roman cement being produced if calcined to a red heat and Portland cement if the calcining is carried to a white heat.

347367—August 17, 1886. J. Murphy and N. W. Lord. *Hydraulic cement.*

It consists of limestone, furnace slag, salt, and clay mixed, burned, and ground.

350415—October 5, 1886. U. Cummings. *Hydraulic cement.*

The process of hydrating hydraulic lime or cement consists in exposing the calcined and pulverized material, while in motion or agitation, to an atmosphere of steam.

358437—March 1, 1887. James and John D. Druecker. *Process of burning lime.*

The hot air is drawn from the top of the kiln and forced back to the fire by means of a blast.

373992—November 29, 1887. S. Lowden. *Manufacture of cement.*

First, a mixture of clay, 1 part, and chalk or limestone, 5 parts, is burned at a white heat and crushed; second, limestone is crushed separately and roasted at about 210° F.; and third, the products are mixed in the proportion of 3 parts of the first to 1 part of the second.

375599—December 27, 1887. R. Bosse, E. Friese, and F. Wolters. *Hydraulic and other cements.*

A cement composed of blast-furnace or other slag reduced to granular form, sand, and slaked lime, with or without silicic acid. Also process of making same.

382376—May 8, 1888. J. Murphy. *Hydraulic cement.*

Same as No. 347367, with the omission of the salt.

387199—July 31, 1888. G. L. Eagan. *Hydraulic cement compound.*

A combination of lime rock, silex, mineral magnesite, and alumina.

387588—August 7, 1888. C. R. Costling. *Process of manufacturing hydraulic cement.*

The cement material is crushed and ground, mixed with water to a plastic state and reground in this condition, next dried in a suitable chamber, and then calcined and again ground.

394663—December 18, 1888. J. T. Rigby. *Manufacture of cement from lime-mud.*

Lime-mud, the residue of alkali works, is washed and treated with carbonic acid, until sulphureted hydrogen ceases to be given off and then with sufficient alkaline silicate to decompose the alkaline-earth chlorides, when it is mixed with clay for the manufacture of cement.

397373—February 5, 1889. R. W. Lesley. *Manufacture of cement.*

In the manufacture of cement from slags, the lime or other ingredients, in a finely divided condition and at a high heat, are injected into the slag while still fluid.

399496—March 12, 1889. G. E. Carleton. *Method of calcining rock.*

An air blast is induced underneath the fuel to increase the draft, and a spray of steam or water within the arch above the fuel to regulate the heat.

402511—April 30, 1889. U. Cummings. *Cement.*

A hydraulic cement consisting of silicate of magnesium calcined and pulverized.

417634—December 17, 1889. G. Duryea. *Process of manufacturing cement.*

Fluorspar is mixed with cement-producing materials.

420371—January 28, 1890. J. M. Willcox. *Method of burning cement making materials.*

The cement making material in a kiln or chamber is subjected to the simultaneous action of the usual solid fuel, mixed with the material and forming part of the charge, and of auxiliary burning jets of gas or liquid fuel, applied to the upper strata of the charge before or about the time the lower strata are lighted.

427380—May 6, 1890. E. N. Trump and D. W. Peck. *Method of establishing units of measure in compounding Portland cement.*

Each ingredient is separately molded or cut into forms of uniform size, the sizes varying according to the proportions in which they are to be compounded.

434830—August 19, 1890. W. Joy. *Method of feeding cement kilns.*

Quantities of slurry and fuel mixed and quantities of neat slurry are separately deposited on the burning mass in the kiln at different times as the burning proceeds.

446911—February 24, 1891. H. C. Baum. *Process of manufacturing Portland cement.*

Quicklime is added to wet calcareous marl, and through the resulting chemical action the mixture is rendered perfectly dry preparatory to grinding.

449510—March 31, 1891. G. Williams. *Process of manufacturing cement.*

Carbonate of lime is reduced to powder by steam, under pressure produced from a solution of silicate of soda and water; alumina, silex, and a thin paste of calcium chloride, unslaked lime, and warm water, are then added and the mixture is molded, calcined, and ground.

450750—April 21, 1891. J. B. Speed. *Process of manufacturing hydraulic cement.*

The rock is crushed and sized by screening, and the furnace charged with lumps of a uniform size.

453753—June 9, 1891. E. F. Baude. *Manufacture of Portland cement.*

To obtain pure lime for the manufacture of Portland cement from blue limestone, the limestone is first calcined; the calcined lumps are next moistened by dipping in water and quickly removing them, so that only the pure lime will slake; and the pure, slaked lime is then separated from the impure by sifting.

455376—July 7, 1891. H. H. Wing. *Manufacture of cement.*

A mixture composed of a phosphate, as calcium phosphate, and a silicate, such as clay or serpentine, the phosphate predominating (say 100 parts of phosphate rock to 46.29 parts of clay), is calcined.

460509—September 29, 1891. G. H. Kolteyer and G. W. Bartholomew, Jr. *Process of preparing and tempering slurry for Portland cement.*

Freshly dug clay and lime materials are mixed in proportions determined by weight, worked while soft, damp, or wet, a portion of the mixed mass tested to determine proportions, and the proportions corrected, if necessary, by adding material.

460697—October 16, 1891. J. H. Wright. *Hydraulic lime.*

Lime, slaked in a solution of crude potash, crude soda ash, and alum which has been boiled and cooled, is mixed with an equal quantity of lime slaked by dipping or sprinkling with sulphuric acid or with plaster of Paris, and the mixture is ground to a powder.

464515—December 8, 1891. J. F. Navarro. *Process of manufacturing hydraulic cement.*

The raw ground rock is burned in a vertical kiln and pulverized; the required additional element is then added, the pulverized mixture is calcined in a rotary kiln, and the product is ground.

464516—December 8, 1891. J. F. Navarro. *Process of manufacturing Portland cement.*

Argillaceous rock containing the constituents of Portland cement is ground in a dry state; when deficient in lime, a definite proportion of cement rock high in lime, or of pure limestone ground raw, is added; the powders are mixed dry and calcined in a rotary kiln, and the clinker is ground.

465330—December 15, 1891. C. Tomkins. *Process of manufacturing cement.*

Highly heated slag as it comes from the furnace and before cooling is subjected to a bath of hydrate of lime, and then dried and pulverized.

486165—November 15, 1892. H. J. Livingston. *Composition of matter for producing Portland cement.*

It consists of 11 parts of shell containing 90 per cent and upward of carbonate of lime, 2 parts of alluvial clay, and 1 part of ground chalk flints.

486706—November 22, 1892. C. Van Forell. *Artificial Portland cement.*

Pulverized Roman cement is mixed with pure hydrate of calcium in the form of a dry powder so that the lime and the hydraulic factors are in the proportion of 17 to 10.

486707—November 22, 1892. C. Van Forell. *Artificial Roman cement.*

Pulverized Roman cement containing an excess of lime is mixed with powdered silicate of aluminum so that the lime and the hydraulic factors are in the proportion of 17 to 10.

491280—February 7, 1893. B. Dreyfuss. *Cement.*

A mixture of 2 parts of pulverized spent lime and 1 part of pulverized coke slag, with one-twentieth of its weight of slaked rock lime, and sand.

494763—April 4, 1893. V. F. L. Smith. *Cement.*

A dry-ground mixture of ordinary cement with sand, gravel, or other filling material.

497785—May 23, 1893. M. L. Griffin. *Manufacture of Portland cement.*

Precipitated carbonate of lime, produced by the addition of lime to a soluble carbonate, such as sodium carbonate, is mixed with clay or other aluminous material, dried, calcined, and ground.

506029—October 3, 1893. J. F. Barrow. *Production of lime.*

The products of combustion are exhausted from the bosh of the kiln, so that air may enter the furnace without mixing to an appreciable extent with the said products.

511938—January 2, 1894. S. Dentler. *Manufacture of cement.*

It is composed of slaked lime, carbonate of potash, sulphate of copper, and sulphate of iron.

515017—February 20, 1894. E. L. Ransome. *Slaking lime.*

The clinker produced in burning combustible material containing lime is slaked, disintegrated, and cooled by passing steam through the burned mass before it is withdrawn from the furnace.

515757—March 6, 1894. G. J. Everett. *Cement compound.*

It is composed of a cement which is itself hydraulic, chloride of calcium, and lime.

523645—July 24, 1894. B. K. Rigby. *Manufacture of cement.*

"Ammonia-soda," or "Chance" waste is washed to remove soluble impurities, then tested chemically, and lime added until the impurities, other than soda and sodium chloride, are below 3.5 per cent, when it is mixed with aluminous material, calcined, and ground.

526910—October 2, 1894. B. K. Rigby. *Manufacture of cement.*

A mixture of Le Blanc lime, mud, and clay is calcined until overburning takes place and then ground.

530247—December 4, 1894. G. W. A. Stein. *Method of manufacturing hydraulic cement.*

From 5 to 10 per cent of slag, sand, and hydrate of lime is mixed with the raw cement materials to prevent disintegration before burning in a kiln.

543452—July 23, 1895. H. H. Pierce. *Process of treating lime.*

Quicklime is slaked to a putty, then roasted and ground.

544706—August 20, 1895. J. Whiting. *Manufacture of cement.*

It is composed of pulverized blast-furnace or other slag, caustic soda, and slaked lime, all in the dry state.

545552—September 3, 1895. W. R. Taylor. *Apparatus for burning cement making materials and process of obtaining carbon dioxide.*

The materials are heated in direct contact with gaseous products of combustion until the moisture, organic matter, and the like are drawn off and the temperature reached at which carbonic acid is given off, when the heating is continued out of contact with the gaseous products of combustion.

550619—December 3, 1895. E. H. Hurry and H. J. Seaman. *Process of and apparatus for manufacture of cement.*

The cement material is roasted, the hot clinker partially cooled, broken, and wetted, and the moisture evaporated from the broken material in a continuous process.

562982—June 30, 1896. G. W. A. Stein. *Hydraulic cement.*

A small quantity of ground slag sand or granulated furnace slag is added to a finished mixture of raw cement to make the sintered mixture brittle, so that on cooling the mass crumbles.

568599—September 29, 1896. C. Bonneville. *Method of and apparatus for calcining cement.*

Raw cement material and cement proper are combined with a combustible material, in an intimately mixed and plastic mass, and are then subjected to a simultaneous rolling and calcining operation by which the mass is formed into separate lumps immediately before, and the combustible material burned out upon and immediately after the setting of the cement proper.

569833—October 20, 1896. S. Jorgensen. *Slag cement.*

To ordinary slag cement, which is composed of ground slag and slaked lime, is added a roasted and powdered mixture of ground slag, slaked lime, and water.

582068—May 4, 1897. R. W. Lesley. *Hydraulic cement.*

To produce a slow-setting Portland cement the cement making material, after calcination, and in the form of either clinker or powder, is treated with dilute sulphuric acid.

584397—June 15, 1897. M. W. L. Nahnsen. *Manufacture of cement.*

The residues from the manufacture of sulphate of aluminum are freed from components soluble in water and the remainder mixed with lime, without being burned.

590057—September 14, 1897. W. H. Fahrney. *Method of calcining friable materials.*

The material to be calcined is formed into a tube and continuously projected into the furnace, the heat of which passes up through the tube.

592492—October 26, 1897. V. Kjeldsen. *Cement manufacture.*

From 3 to 5 per cent of manufactured cement is added to the raw material and the mixture formed into blocks, which are burned and ground.

599792—March 1, 1898. H. H. Pierce. *Process of treating lime.*

Quicklime is slaked to a putty, roasted in the presence of carbonic acid gas, and ground.

606278—June 28, 1898. C. J. Curtin. *Process of making slag cement.*

Burnt lime, to which has been added 3 per cent of hydrochloric acid, is immersed in about 20 per cent of water, thoroughly mixed and combined with 85 per cent of molten slag, and then dried and pulverized.

617241—January 3, 1899. A. D. Elbers. *Process of treating blast-furnace slag for cement.*

Pulverized blast-furnace slag is superficially desulphurized by the application of a weak solution of nitric acid, and then alkalized by impregnation with an aqueous solution of sodium carbonate.

620155—February 28, 1899. H. J. Livingston. *Composition for making carbonated, hydraulic lime, cement, or mortar.*

It consists of 100 parts of hydrate of lime, 30 to 40 parts of coke, and 1 part of saccharine or farinaceous matter by weight.

622387—April 4, 1899. H. H. Pierce. *Cement.*

Quicklime is slaked to a putty; pulverized sulphate of lime is then added, the mixture is roasted, and the roasted product is then reduced to a powder.

622388—April 4, 1899. H. H. Pierce. *Treatment of lime.*

Quicklime is slaked to a putty; pulverized carbonate of lime is then added, the mixture is roasted, and the roasted product is reduced to a powder.

636865—November 14, 1899. C. Straub. *Process of treating calcium oxide.*

Calcined lime is partially hydrated, and then recalcined until all moisture is expelled.

643856—February 20, 1900. W. S. O. Muth. *Manufacture of cement.*

Burnt lime is hydrated with water containing a soluble salt which will evolve oxygen at a high temperature, such as nitrate of soda, and the hydrated lime is mixed with powdered blast-furnace slag, and then calcined.

651684—June 12, 1900. G. M. Westman. *Process of manufacturing lime and carbonic acid.*

The process consists in heating a mixture of carbonic acid and steam, passing this mixture through limestone, drawing off the expelled carbonic acid and lime produced, bringing the expelled carbonic acid in contact with water to convert the latter into steam and form a mixture of steam and carbonic acid, reheating a part of the mixture thus formed, and forcing the mixture back into and through the limestone.

655501—August 7, 1900. L. H. M. Merceron-Vicat. *Artificial cement.*

Marly limestone is calcined, and then fused under oxidizing conditions, thereby removing the sulphur while in a state of fusion.

667255—February 5, 1901. A. S. Schubert and F. J. Pierce. *Process of producing lime and cement and fixed combustible gases.*

The gases distilled off from a mass of raw cement and fuel are passed through a mass of incandescent carbonaceous material, from which air is excluded; the residuum is subsequently clinkered, the heat evolved in the clinkering process being utilized for distilling and partially burning a subsequent charge.

670047—March 19, 1901. G. M. Westman. *Process of manufacturing lime and carbonic acid.*

This is a continuous process of treating limestone with a highly heated mixture of carbonic acid and steam, consisting in expelling the carbonic acid from the limestone, bringing the hot carbonic acid in contact with water to convert the latter into steam, mixing the steam with the expelled carbonic acid, and then reheating the mixture and again passing it through the limestone, thus producing lime and carbonic acid of maximum purity.

678412—July 16, 1901. W. Lessing. *Process of burning cement, gypsum, etc.*

The raw material is ground, heated to a white heat, and dropped downward against a column of flame; it is then utilized, in its intensely heated condition, to generate steam for the preliminary warming of fresh material.

678748—July 16, 1901. G. Miller. *Process of forming pieces of raw cement.*

Pieces of dried cement are passed successively through a series of drying drums, each containing a plastic mass of raw cement.

682837—September 17, 1901. C. M. Avery. *Process of pulverizing calcium oxide or lime.*

The lime, as it comes from the kiln, is subjected to simultaneous agitation and sifting in the presence of steam.

683188—September 24, 1901. F. N. Spear. *Process of treating lime.*

Finely divided quicklime is subjected to the action of steam in a closed chamber, and then brought into contact with carbonic acid gas obtained from a calcining kiln.

685064—October 22, 1901. A. S. Schubert. *Process of producing lime or cement and combustible gases.*

Heated products of the combustion of burning fuel are passed through raw cement material, thereby expelling gaseous matter therefrom, the resultant gases being subsequently passed through a body of highly heated fuel.

688910—December 17, 1901. G. Warren. *Manufacture of cement or similar materials.*

The liquid sludge is run into molds and dried, to form blocks for calcination.

691397—January 21, 1902. J. D. McDonnell. *Cement.*

It consists of water, carbolic acid, nitro-muriatic acid, nitric acid, crushed calcareous rock, sulphate of calcium, and cement of any manufacture.

692257—February 4, 1902. C. E. Eldred. *Method of calcining lime, etc.*

In place of the ordinary pure-air draft, an artificially accelerated draft composed of air and a neutral gaseous diluent—kiln gases—is

used to promote combustion, thereby greatly retarding the liberation of the heat units of the fuel and producing a long flame of large volume.

698268—April 22, 1902. O. Friz. *Process of making cement.*

To produce a white cement, a mixture of lime, clay as free as possible from iron, and feldspar is burned to the verge of fusion—that is, beyond the sintering limit.

702009—June 10, 1902. F. G. Jordan. *Process of making cement.*

Limestone is decarbonated and siliceous clay mixed therewith while in an incandescent state; the mixture is then ignited in the presence of a hydrating agent, molded, calcined, and ground.

704849—July 15, 1902. J. T. McKim. *Cement.*

A compound to be added to Portland or similar cement, consisting of calcareous ocher, iron ore plant, and litharge, ground and subjected to a heat of 160° F.

705542—July 22, 1902. M. T. J. Ochs. *Plaster composition.*

It consists of a mixture of 2 parts of hydraulic cement, 1 part of powdered silicate of aluminum, and 1 part of powdered carbonate of lime.

705650—July 29, 1902. V. Conti, G. De Geofrey, and G. Le Gall du Terte. *Artificial stone.*

A mixture of 15 parts of aluminum sulphate, 15 parts of pulverized Kieselguhr, 50 parts of calcined magnesia, 25 parts of magnesium chloride, and 75 parts of magnesium sulphate, all by weight, together with inert matter.

706760—August 12, 1902. W. R. Knox. *Hydraulic fireproof cement.*

A ground but unburned mixture composed of about 24 parts of silica, 6½ parts of alumina, 5 parts of magnesia, 60 parts of lime, 3 parts of hydrochloric acid, and 1½ parts of iron oxide.

707788—August 26, 1902. J. Murphy. *Composition of matter.*

It consists of crushed, hard iron slag, pulverized hard-limed cinders, Portland cement, liquor of flints, and water.

714842—December 2, 1902. R. F. Wentz. *Art of manufacturing cement.*

Cement ore is calcined by the combustion of pulverized carbon, utilizing also the heat from the gaseous products, derived from the disintegration of highly heated cement clinker when treated with water and air.

CLAY

CLAY.

By Jefferson Middleton.

This report covers the operations of the clay mining industry in the United States during the year 1902. By far the larger portion of the clay mined is used by the miner in the manufacture of clay products, but as the work of winning the clay is such an intimate part of the process of manufacture as to make its segregation impossible, only the clay mined and sold as such has been included in the report. The statistics for the clay working industries were shown in the Twelfth Census Report on Manufactures.

The clay mining industry seems to have received but little attention at previous censuses. Statistics were first shown at the census of 1860, when 5 mines were reported, all in Middlesex county, N. J., with a product valued at $105,660. At the census of 1870, 1 fire clay establishment was reported from Jackson county, Mich., with a product valued at $80,000. At the census of 1880 statistics were presented for 9 kaolin mines—4 in Delaware, 2 in South Carolina, and 1 each in Indiana, Maryland, and New York—reporting 23,277 tons of clay, valued at $200,457. The Eleventh Census contains no statistics for clay mining as a distinct industry.

Clay mining was carried on in 27 states, but in most of them the industry was of minor importance. In only 6 of the states did the product exceed a value of $100,000, and the product for these states was 68.7 per cent of the total value of products for the United States.

The following table is a summary of the statistics for 1902:

Table 1.—*Summary: 1902.*

Number of mines	205
Number of operators	203
Salaried officials, clerks, etc.:	
Number	185
Salaries	$150,505
Wage-earners:	
Average number	2,433
Wages	$958,892
Contract work	$13,241
Miscellaneous expenses	$126,873
Cost of supplies and materials	$272,823
Product:	
Quantity, short tons	1,455,357
Value	$2,061,072

While there were 205 mines reported, they were owned by 203 operators, showing that the clay mining industry is as yet largely local, the modern tendency to combination not having affected it. Of the mines, 34 were in New Jersey, 31 in Ohio, and 25 in Missouri. The number in the other states varied from 19 in Pennsylvania to 1 in several of the states.

In addition to the active mines, 61 idle mines were reported, distributed as follows: 12 in Ohio, 6 in Tennessee, 5 in Maryland, 4 each in Georgia and Pennsylvania, 3 each in Colorado, Missouri, North Carolina, and Virginia, 2 each in California, Illinois, Indiana, Kentucky, Massachusetts, and Vermont, and 1 each in Michigan, New Hampshire, New Jersey, New York, South Carolina, and West Virginia. There were also 2 mines—1 each in North Carolina and Florida—at which development work only was reported.

Capital stock of incorporated companies.—Table 2 presents the details of the capitalization of the 45 incorporated companies reporting capitalization. It shows that of the 203 operators of clay mines 52 were incorporated companies, of whom 45 reported an authorized capital stock of $6,947,600. The total number of shares authorized was 660,536, and the total number of shares issued was 341,107, with a par value of $5,275,200. The dividends paid during the year amounted to $59,190. The authorized stock was divided into 650,986 shares of common stock, with a par value of $6,272,600, and 9,550 shares of preferred stock, with a par value of $675,000. Of the common stock, however, only 332,377 shares (par value, $4,637,200) were issued, while 8,730 shares of preferred stock (par value, $638,000) were issued. The bonds issued were 717 in number, with a par value of $331,000, on which the sum of $18,110 was paid as interest. The only states in which companies reported preferred stock were Georgia, Delaware, and New Jersey, while bonds were authorized and issued only in the two last named states and in Pennsylvania. In West Virginia bonds to the value of $15,000 were authorized, but none were issued. In only 1 state (Wisconsin) were assessments levied.

TABLE 2.—CAPITALIZATION OF INCORPORATED COMPANIES: 1902.

[1] Includes companies distributed as follows: Connecticut, 1; Florida, 2; Massachusetts, 1; North Carolina, 3.

Delaware, New Jersey, and Pennsylvania are the only states showing a capitalization exceeding $1,000,000.

Employees and wages.—The average number of wage-earners employed during each month in 1902 is shown by states in Table 7. The most active clay mining season was from April to October. This is to be expected when the principal method of mining clay is considered. Probably 90 per cent of the work was done in open pits; this tends to reduce operations in the cold months and in inclement weather. The variation in the number of wage-earners between the months of summer and winter is not as great as might be expected, considering the fact that the work done is almost entirely above ground. The average number of wage-earners, men and boys, for the whole year was 2,433. The largest number of men employed in any one month was 2,624 in June, while the smallest was 2,100 in February. The average number of men employed for the whole year was 2,403. The average number of boys employed during the year was 30, the highest number

being 34 in June and July, and the lowest number 27 in October and November. The largest number of men was employed in New Jersey—697 for the entire year, 798 in July, and 590 in February. The average number of men reported for Pennsylvania was 311 for the whole year, with the largest number in June (338), and the smallest in February (274). South Carolina shows an average of 190 for the year, while the average by months ranged from 167 in August to 216 in May. In Delaware the average for the year was 169, while the greatest number, 197, was reported in June and the least, 103, in February.

Table 3 presents the average number of each class of wage-earners employed at specified daily rates of pay in 1902.

TABLE 3.—*Distribution of wage-earners according to daily rates of pay, by occupations: 1902.*

RATE PER DAY (DOLLARS).	All occupations.	Engineers.	Firemen.	Machinists, blacksmiths, carpenters, and other mechanics.	Miners.	Miners' helpers.	Timbermen and track layers.	Boys under 16 years.	All other wage-earners.
Total	2,433	53	19	34	1,649	17	2	30	629
Less than 0.50	11	.....	.....	.....	.....	.....	.....	9	2
0.50 to 0.74	44	.....	.....	.....	1	.....	.....	13	30
0.75 to 0.99	330	.....	1	.....	275	.....	2	5	47
1.00 to 1.24	495	6	2	7	206	.....	.....	3	270
1.25 to 1.49	871	2	3	5	730	2	.....	.....	129
1.50 to 1.74	321	24	10	12	232	8	.....	.....	36
1.75 to 1.99	89	2	2	.....	34	3	.....	.....	48
2.00 to 2.24	121	11	1	8	76	4	.....	.....	21
2.25 to 2.49	65	2	.....	1	53	.....	.....	.....	9
2.50 to 2.74	68	4	.....	1	29	.....	.....	.....	34
2.75 to 2.99	7	.....	.....	.....	7	.....	.....	.....	.....
3.00 to 3.24	10	1	.....	.....	6	.....	.....	.....	3
3.25 to 3.49	1	1	.....	.....	.....	.....	.....	.....	.....

Of the 2,433 wage-earners of all occupations, 871, or 35.8 per cent, received between $1.25 and $1.49 per day; 495, or 20.3 per cent, between $1 and $1.24; 330, or 13.6 per cent, between 75 and 99 cents; and 321, or 13.2 per cent, between $1.50 and $1.74.

Of the total number, 1,648, or 67.7 per cent, were miners, of whom 730, or 44.3 per cent, received between $1.25 and $1.49 per day, and 231, or 14 per cent, between $1.50 and $1.74; while 276, or 16.7 per cent, received less than $1.

The wage-earners next in number to miners were reported as "all other wage-earners." Of these there were 629, consisting largely of unskilled workmen or common laborers, as is indicated by the low rates shown in the table—399, or 63.4 per cent, having been paid from $1 to $1.49 per day. The other classes of occupations were numerically small.

The rates of pay of engineers, firemen, and mechanics averaged somewhat higher than the rates for miners, while the rates paid to boys ranged from less than 50 cents up to from $1 to $1.24.

Mechanical power.—The total horsepower reported for the industry was 4,478, of which 3,942, or 88 per cent, was steam, the remainder being divided between gas and gasoline engines, water wheels, and "other power." Power is used to a less extent, proportionally to production, in the mining of clay than in many of the other mining industries, clay being taken usually from open cuts, with pick and spade, and without the use of machines.

Production.—Table 4 shows the production of clay from 1897 to 1902, inclusive, by varieties.

TABLE 4.—QUANTITY AND VALUE OF EACH KIND OF CLAY PRODUCED: 1897 TO 1902.

[United States Geological Survey, "Mineral Resources of the United States."]

[1] Prepared ball clay included in "miscellaneous."
[2] Includes 39,157 tons of sand, valued at $35,956, produced in connection with the mining of clay.

It is possible that the figures for some of the years are not strictly comparable, because they may include clay sold, in the raw or the prepared state, by those whose principal business was the manufacture and sale of clay products and not the production of clay. This table shows that the production of clay increased from 563,115 tons in 1897 to 1,455,357 tons in 1902, a gain of 892,242 tons, or 158.4 per cent, while the value increased from $978,448 in 1897 to $2,061,072 in 1902, a gain of $1,082,624, or 110.6 per cent. It is probable that the figures for the first two or three years reported by the Survey are somewhat below the actual output, because they were collected by correspondence—a method by which it takes usually two or three years to secure satisfactory results.

While the quantity of the product for 1902 was the largest recorded, being greater by 88,187 tons, or 6.5 per cent, than in 1901, the value of the product decreased from $2,576,932 in 1901 to $2,061,072 in 1902, a loss of $515,860, or 20 per cent. This decrease in value was due largely to a marked decline in the value of prepared fire clay, which showed a decrease of 38.8 per cent in quantity and of 79.8 per cent in value.

Of the 1,455,357 tons of clay mined in 1902, 1,203,369 tons, or 82.7 per cent, were sold without any preparation whatever after mining, while 251,988 tons, or 17.3 per cent, were prepared at the mine by washing, by grinding, or in some other manner. In 1901, 74.5 per cent was sold raw and 25.5 per cent was prepared at the mine. The average value of all clay at the mine in 1902 was $1.42 per ton; the value of the raw clay was $1.10, and of the prepared, $2.94 per ton. In 1901 these average values were $1.89, $1.25, and $3.74, respectively.

Rank of states.—Table 5 shows the distribution of the value of the clay produced during 1902, by states, ranked according to the value of their product.

New Jersey was by far the most important clay mining state, its product being valued at $612,721, or 29.7 per cent of the total. Pennsylvania ranked second with a product valued at $288,811, or 14 per cent; Delaware was third, with a value of $171,714, or 8.3 per cent; and Missouri, South Carolina, and Ohio were fifth, sixth, and seventh, in the order named, with products valued at $134,862, $107,325, and $101,305, respectively, or 6.5 per cent, 5.2 per cent, and 4.9 per cent. The product of these six states was valued at $1,416,738, or 68.6 per cent of the total. In "all other states" are included, however, two rather important clay producing states, namely, Florida and North Carolina. In these states the clay produced was valued at $221,833, or 87 per cent of the total for "all other states," and 10.8 per cent of the total for the United States. The remaining states were of but relatively small importance, none producing clay valued at as much as $100,000.

TABLE 5.—*Rank of states according to value of clay produced: 1902.*

STATE.	Rank.	Value of product.	Per cent of total.
United States		$2,061,072	100.0
New Jersey	1	612,721	29.7
Pennsylvania	2	288,811	14.0
Delaware	3	171,714	8.3
Florida	4	(1)

A detailed summary of the clay mining industry for 1902 is given in Table 7.

DESCRIPTIVE.

Popularly, clay is any earthy substance which, if mixed with water and molded, will retain its shape after drying, and which upon subjection to high temperature loses its plasticity and becomes hard and brittle.

Technically, pure clay or kaolinite, which is the basis of all clay, is a hydrated silicate of aluminum, expressed by the formula $Al_2O_32SiO_2$, $2H_2O$. All clay in its natural state contains more or less impurities, the kind and quantity of which determine its character; from purest varieties, called kaolin, clays range through all stages of impurity down to a point where the material contains so little kaolinite that it can not be classified as clay at all.

Clay is ordinarily classified as kaolin, ball clay, fire clay, vitrified ware clay, and brick clay; there are also slip clay, and paper clay. Fire clay includes clays used for stoneware and for terra cotta, which are reported separately by the Geological Survey. Vitrified ware clay includes the pipe clay reported by the Survey.

In the following description of the physical and chemical properties of the several kinds of clay, the chemical analysis has been supplemented, wherever possible, by what is called the rational analysis. The ordinary quantitative chemical analysis treats clay as a mixture of oxides, although the elements may be present in entirely different combinations, such as silicates, carbonates or hydrates, sulphates, etc. The nature of these combinations is of importance. For example, silica in the form of quartz, which is infusible, will decrease the shrinkage and up to certain temperatures increase the refractoriness; but if present as a component of feldspar, it serves the purpose of a flux and somewhat increases the plasticity. The advantage of the rational analysis is that it resolves the clay into its mineral components, affording an insight into the physical properties—as fusibility, refractoriness—of the material. This is frequently a matter of far greater importance than the chemical composition; for instance, two clays of the same rational composition will behave much alike if burned under the same conditions, even though they may differ in chemical composition.

Kaolin.—Kaolin is a white burning, nonplastic, highly refractory residual clay used in the manufacture of china and other white wares; it must be practically free from iron, as a very small quantity would cause the ware to become discolored in burning. The chief producing states are Pennsylvania, Delaware, North Carolina, and South Carolina. The following is an analysis of a washed sample of the kaolin from North Carolina, which is one of the best known and most widely used.

Analysis of washed kaolin from North Carolina.[1]

	Per cent.
Silica	45.70
Alumina	40.61
Ferric oxide	1.39
Lime	0.45
Magnesia	0.09
Alkalies	2.82
Moisture	0.35
Water (loss on ignition)	8.98
	100.39
Free sand	3.19
Total fluxes	4.75
Specific gravity	2.43

The rational analysis is as follows:

Clay substance	96.81
Quartz	0.07
Feldspar	3.12
	100.00

[1] North Carolina Geological Survey, Bulletin No. 13, page 61.

Ball clay.—Ball clay is a white burning, plastic, sedimentary clay, used with kaolin to afford plasticity to the body in the manufacture of white ware, and often incorrectly called kaolin. The distinguishing characteristic of this clay is its plasticity. The chief producers of ball clay for sale are Florida, New Jersey, and Kentucky.

The following is an analysis of ball clay from Florida:

Analysis of ball clay from Florida.[1]

	Per cent.
Silica	46.11
Alumina	39.55
Ferric oxide	0.35
Magnesia	0.13
Sulphuric oxide	0.07
Titantic oxide	1.20
Water	13.78
	101.19

[1] United States Geological Survey, Professional Paper, No. 11, page 39.

Fire clay.—The term fire clay is a rather broad one, embracing not only the high-grade clays used for the manufacture of refractory material of all kinds, but also the more or less impure varieties used for stoneware, terra cotta, and yellow and Rockingham ware. Glass-house supplies, which must be highly refractory, are made from an especially high grade of this clay. Fire clay is subdivided into flint, or nonplastic, and plastic clay. The mining of fire clay for sale is most extensively carried on in New Jersey, Missouri, Pennsylvania, and Ohio.

Analyses of various fire clays.

Vitrified ware clay.—Clays for vitrified wares, such as sewer pipe, electric conduits, and vitrified paving brick, are those in which the proportion of fluxing impurities is sufficient to allow the clay to vitrify at a moderately low temperature, but not to cause the ware to become soft under the pressure of a column of some height and considerable weight. The following table shows the range of the constituents of clays used for making vitrified paving brick, together with an average analysis of such clays:

Analysis of vitrified paving brick clay.[1]

	Minimum (per cent).	Maximum (per cent).	Average (per cent).
Silica	49.00	75.00	56.00
Alumina	11.00	25.00	22.50
Ferric oxide	2.00	9.00	6.70
Lime	0.20	3.50	1.20

Alkalies	1.00	5.50	3.70
Ignition loss (mainly water)	3.00	13.00	7.00

[1] Vitrified Paving Brick, by H. A. Wheeler, page 18.

Brick clay.—Brick clays are divided into those used for common and for pressed and ornamental brick. Red earthenware, such as flowerpots, is also made of brick clay. Clays suitable for the manufacture of common brick are located in every state and almost every county in the Union. Of all clays these are usually the most impure, often containing a rather high percentage of lime. Lime in a finely divided state is not harmful; but in the form of limestone pebbles it is very injurious to the finished product, as the process of burning converts these pebbles into quicklime, which is apt to slack, thus breaking the brick, upon being exposed to the atmosphere. This difficulty is sometimes overcome by passing the clay through a pulverizer, which crushes the pebbles, or by screening it to remove them. The following table shows the range of the constituents of clays used in the manufacture of common building brick, together with an average analysis of such clays:

Analysis of common brick clay.[1]

	Minimum (per cent).	Maximum (per cent).	Average (per cent).
Silica	34.35	90.877	49.27
Alumina	22.14	44.00	22.774
Ferric oxide	0.126	33.12	5.311
Lime	0.024	23.20	2.017
Magnesia	0.02	11.03	2.66
Alkalies	0.17	15.32	2.768
Water	0.05	13.60	5.749
Moisture	0.17	9.64	2.502

[1] New York State Museum, Bulletin No. 35, page 639.

Pressed brick and ornamental brick require a higher grade of clay, the buff varieties being made sometimes from a refractory or semirefractory clay. The buff color in refractory clay is due to the low percentage of iron; in other clays, notably the Milwaukee clay, from which is made, probably, the best known buff or cream brick, it is due to a large percentage of lime, which enters into chemical combination with the iron, thus neutralizing its coloring effect.

Slip clay.—Slip clay is used in glazing low grade products such as earthenware and stoneware. It must fuse at a low temperature and produce a glaze of even color. The clay generally used for this purpose is mined near Albany, N. Y., and hence is known as Albany slip. It produces a dark brown glaze, and is shipped to almost every state in the Union.

Paper clay.—Paper clay is used, as its name indicates, in the manufacture of paper. As clay used for this purpose is not molded or fired, plasticity, fusibility, and vitrifying qualities need not be considered; hence any pure white, smooth, gritless clay can be used. Where the clay is suitable in color, but gritty, the grit is sometimes washed out. In the United States paper clays are mined in Delaware, Georgia, Maryland, Pennsylvania, and Wisconsin.

The following is an analysis of so-called kaolin from Wisconsin, used in paper manufacture:

Analysis of paper clay from Wisconsin.[1]

	Per cent.
Silica	52.41
Alumina	34.10
Ferric oxide	0.15
Lime	0.05
Magnesia	0.12
Alkalies	0.64
Titanic oxide	0.80
Combined water	11.89
	100.16

[1] Wisconsin Geological and Natural History Survey, Bulletin No. 7, page 272.

Methods of mining.—There are several methods of mining clay, but only two are generally followed, viz, open pit and underground mining. Open pit mining is conducted in several ways—with pick and shovel, with a scraper, or by falling the clay, that is, by undermining it and letting it fall. Sometimes explosives are used for the last-named purpose.

In underground clay mining the methods of working are the same as those usually followed in coal mining, namely, by shaft or tunnel, with drifts, slopes, and chambers; there are, however, comparatively few deep mines in the clay industry, except where the clay is mined in connection with coal. Kaolin is sometimes mined by sinking through the vein a round shaft, the sides of which are timbered.

Preparation.—The commoner grades of clay are generally sold as mined, because to prepare them for the market in any way would add so greatly to their cost as to make them unprofitable. Even the common clays, however, are sometimes screened or ground to get rid of limestone pebbles or other small stones; screening removes them mechanically, while grinding overcomes their bad effects through comminution. In this country the common clays are not washed. The kaolins and ball clays are, however, sometimes washed at the mines, but they are again washed or prepared at the

pottery before being manufactured into white ware.[1] Another method of separating the clay from its undesirable impurities is by fans. This method can only be employed where the impurities are in the form of coarse particles or grains of sand, and consists in first grinding the clay to a very fine powder, after which it is carried to a flue through which a strong current of air is forced; this immediately carries the finer particles to the end of the flue where they are dropped into a bin. The coarser particles are dropped into the flue and carried back to the pulverizer to be ground over again. In the manufacture of pottery, and also of brick by the dry press process, the clay is cured, or weathered, often for months, before being used.

Uses.—Clay is used most extensively in the manufacture of common building brick; next in importance, as measured by the quantity of material consumed, is front or pressed brick, with its almost limitless variety in color and shape. Then there are vitrified brick, with a large and growing field of usefulness, and fire brick, the shape and utility of which are almost without limit, stove lining being an important subdivision. Other important products are drain tile, sewer pipe, ornamental terra cotta, fireproofing, roofing tile, flooring tile, and encaustic tile.

In addition there are assayers' supplies, boiler and locomotive tile and tank blocks, building blocks, burnt clay ballast, chemical brick, patent chimney brick, chimney pipes and tops, clay furnaces and retorts, conduits for underground wires, crucibles, cupola bricks, fence posts and fence post stubs, flue linings, frost proof cellar brick, gas logs and settings, glass-house furnace blocks, grave markers, muffles, porous cups, runner brick, sidewalk tile, souvenirs, stone pumps, terra cotta vases, tile mantels, wall coping, washboards, and well brick and tile.

In addition to the well-known pottery products of clay, such as red earthenware, stoneware, yellow and Rockingham ware, and the various grades of white ware from C. C. ware to china, the following wares also are made of clay: Acid proof tanks, art and chemical pottery, bath tubs, caster wheels, electrical supplies, faience glass pots, insulators, jardinieres, lavatories, pins, stilts and spurs for potters' use, porcelain hardware trimmings, shuttle eyes and thread guides, pump stands, and wash tubs.

[1] For description of methods of washing clays, see New York State Museum, Bulletin No. 35.

ABRASIVE MATERIALS

ABRASIVE MATERIALS.

By Joseph Hyde Pratt.

The mining of abrasive materials forms a very important industry among the minor minerals, on account of their close connection with all manufacturing industries. As a whole, these abrasive materials are but little understood, although they are of widespread use. No manufacturing plant, machine shop, blacksmith shop, farm, or household is without some form of abrasive, so that these materials are perhaps in as universal use as any group of minerals. While the abrasive materials vary widely in character and occurrence, they can readily be grouped together and considered under one head on account of the similarity of their use. The natural products that are used for abrasive purposes are as follows: Buhrstones and millstones (conglomerate and granite); corundum and emery; crystalline quartz; garnet; grindstones and pulpstones (sandstone); infusorial earth, tripoli, and pumice; and oilstones, whetstones, and scythestones (sandstone and schist).

The crystalline quartz included in this report is used in the manufacture of sandpaper, scouring soaps, wood-finishing materials, etc., and does not include that used in the pottery and glass industries, and which is included in the report on flint and feldspar. On the other hand, the entire production of infusorial earth and tripoli is included in these statistics because the small production of these materials, although but little is actually used for abrasive purposes, does not justify separate treatment.

In treating these mineral products under the one subject of abrasives it is not always feasible to give detailed statistics regarding each, as would be done if they were treated separately, and proper comparisons between expenditures on account of the production of the different abrasives can not always be made, because some of the articles require more elaborate processes than others in their preparation for market. At none of the previous censuses have the abrasive materials been grouped as they are in this report. The statistics of mining operations for some of these minerals were reported for 1880 and 1889, but they were not brought together in a single class.

At the census of 1880 the classifications of abrasives were, corundum (emery), garnet, infusorial earth, oilstones, scythestones, and whetstones. At the Eleventh Census the classifications were, corundum, grindstones, infusorial earth, millstones, and whetstones.

In Table 1 are given the statistics for these several classifications for the censuses of 1902 and 1889, and while not comparable, yet they indicate in some measure the growth in the production of abrasive materials for this period. For corundum and emery, and also for oilstones, whetstones, and scythestones, comparisons of most of the items can be made for the two censuses.

Buhrstones and millstones to the value of $1,425, included in the statistics for 1902, were quarried at granite quarries; grindstones and pulpstones to the value of $403,066, and oilstones, whetstones, and scythestones to the value of $38,612 at sandstone quarries; and infusorial earth, tripoli, and pumice to the value of $1,436 at talc and soapstone mines, all as by-products. In these cases the wages and other expenses of production are included in the statistics for granite, sandstone, and talc and soapstone, respectively.

The production of certain of these abrasives is on the decline, while that of others is increasing, but because of the increase in manufacturing industries the aggregate amount of abrasive materials used in the United States is greater than ever before. As their use is limited there could easily be an overproduction of most of them, but in the aggregate there will be an increasing demand from year to year. This will depend principally upon the growth of our manufacturing industries and the development of our agricultural lands, and with an increase or a decrease in manufacturing especially there will be a corresponding change in the production of abrasives. The principal change, however, that will be noticed is in the amount of the different kinds of abrasives used from year to year, the production of some increasing rapidly, others steadily decreasing, these variations being due to the introduction of new natural or artificial abrasive products, to changes in methods of manufacturing, and to the use of new types of machinery, affecting principally the abrasives formerly used for agricultural implements.

TABLE 1.—COMPARATIVE SUMMARY: 1902 AND 1889.

	Year.	All abrasives.	Buhrstones and millstones.	Corundum and emery.	Crystalline quartz.	Garnet.	Grindstones and pulpstones.	Infusorial earth, tripoli, and pumice.	Oilstones, whetstones, and scythestones.

[1] Not reported.
[2] Included in wage-earners and wages.
[3] Included with statistics for sandstone.
[4] Includes foremen; their salaries are included in wages.
[5] Number of pieces.
[6] The United States Geological Survey reports $1,326,755, which includes products finished elsewhere than at the quarry.

During the past fifteen years, many experiments and investigations have been made with a view of producing artificial abrasives that would be equal to or superior to the natural products. As a result of these experiments there are now four artificial abrasives on the market—carborundum, crushed steel, alundun (artificial corundum), and adamite. The value of the artificial abrasives produced and used in the United States during 1902 was over $300,000, and will illustrate the extent to which these artificial products are being utilized at the expense of natural products.

As shown by Table 1, of the 82 mines or quarries producing abrasive materials in 1902, 29 are credited to buhrstones and millstones, this being due not to the large production of this type of abrasive, but to the fact that there were a great many individual operators in the New York field producing a small number of buhrstones. Grindstones and pulpstones are credited with only 9 mines or quarries, although the value of their production is greater than the value of the combined production of all the other abrasives.

These 82 mines or quarries were worked by 75 operators, there being 39 individuals, 17 firms, and 19 incorporated companies. Twenty-three of the 39 individual operators were producers of buhrstones and millstones. The next largest number of individual operators were the 7 producing oilstones and whetstones.

There were 35 mines or quarries that have produced abrasive materials of some kind during the past few years from which no production was reported for 1902. These were distributed among 16 states, from Maine to California. Nineteen were owned by individuals, 11 by firms, and 5 by incorporated companies. The capital stock issued by the incorporated companies amounted to $258,000, all of which was reported for the corundum and emery industry. While some of these idle plants may have shut down permanently, others will probably be producers again in another year or two. Development work, without production, was reported by 1 corundum and emery mine.

Capital stock of incorporated companies.—No definite comparisons can be made of the statistics of the incorporated companies producing abrasives, for the reason that the corporations are not always confined simply to the production of an abrasive material. Thus, in the case of the grindstone industry, the companies producing the greater amount of this abrasive are also producers of building stone, which is their principal product, the manufacture of the grindstones being the smaller part of their business. The details of their capitalization are, therefore, given under sandstones in the report on "Stone."

In Table 2 are given the details of the capitalization of the 19 incorporated companies producing abrasives.

TABLE 2.—CAPITALIZATION OF INCORPORATED COMPANIES, BY KINDS OF ABRASIVES: 1902.

	All abrasives.	Corundum and emery.	Crystalline quartz.	Garnet.	Grindstones and pulpstones.	Infusorial earth, tripoli, and pumice.	Oilstones, whetstones, and scythestones.

Interest paid	$24,000	$24,000					

The total par value of the capital stock and bonds issued by the incorporated companies was $5,545,900. The tendency toward incorporation is most evident in the companies mining garnet and corundum and emery, but the capitalization reported for these companies includes also, in part, the amount utilized for the subsequent manufacturing process. These industries, too, are the only ones reporting a bonded indebtedness. Four companies producing corundum and emery reported a capital stock and funded debt amounting to $2,365,800, and three companies producing garnet reported $2,412,000 for the same items. No incorporated companies were reported as engaged in producing buhrstones and millstones.

Crystalline quartz; grindstones and pulpstones; infusorial earth, tripoli, and pumice; and oilstones, whetstones, and scythestones show a comparatively small average capitalization. Dividends amounting to $10,000 were paid on the common stock of crystalline quartz companies, and a like amount on the common stock of companies producing infusorial earth, tripoli, and pumice. Companies producing corundum and emery paid the sum of $10,860 as dividends on preferred stock, and $24,000 as interest on bonds having a par value of $430,000.

Employees and wages.—The total average number of employees engaged in the abrasive industry during 1902 was 685, of whom 75, or 10.9 per cent, were salaried employees, and 610, or 89.1 per cent, wage-earners. These received in salaries and wages $344,922, of which $48,008 was received by the salaried employees and $296,914 by the wage-earners. The classification of these salaried employees and wage-earners is shown in Tables 4 and 5.

Of the 610 wage-earners, only 25, or 4.1 per cent, were employed below ground, and of this number 22 were employed in the corundum and emery industry. The other 3 wage-earners below ground were engaged in the infusorial earth industry. All the other abrasives are obtained by means of open cuts and pits. Because of this the operations are of necessity somewhat curtailed during the winter months. As is seen in Table 4, the monthly average number of wage-earners employed during January, February, and March ranged from 429 to 478, while during the remaining months of the year the range was from 596 to 703. The daily rates of pay of the wage-earners, also shown in Table 4, varied from 75 cents to $4.24, the lowest wages being paid principally to the miners or quarrymen and the highest to the engineers and machinists.

Of all the wage-earners, 212, or 34.8 per cent, received from $1.50 to $1.74 per day, and of these, 160, or 75.5 per cent, were miners or quarrymen. Twenty-six per cent of the wage-earners received less than $1.50 per day. Of the total number 6.5 per cent were classified as engineers, of whom the greater number received from $2 to $2.24 per day; 402, or 65.9 per cent, were returned as miners, their wages varying from 75 cents to $3.24 per day. Only 10 miners' helpers were reported, but it is very probable that the actual number of this class of wage-earners was considerably in excess of this figure, since many of them were included under "all other wage-earners." It will be noticed that in this industry the question of child labor

is unimportant, as only 3 boys under 16 years were employed.

Supplies, materials, and miscellaneous expenses.—The total cost of the supplies and materials used in the mining and quarrying of the abrasive materials produced in 1902 was $80,309. Of this amount, $31,349, or 39 per cent, was used in the grindstone industry, and $26,114, or 32.5 per cent, in the corundum and emery industry.

The miscellaneous expenses amounted to $42,410, of which $8,421 was paid out for royalties and rent of mine and mining plant, and $33,989 for rent of offices, taxes, insurance, interest, and other sundries.

Mechanical power.—Of the primary power reported, 2,300 horsepower, or 92.2 per cent, was steampower applied by 71 steam engines. Forty-one steam engines, having a total of 1,235 horsepower, were used in the grindstone and pulpstone industry. The next largest number of steam engines, 13, was reported for the oilstone, whetstone, and scythestone industry, but these aggregated only 185 horsepower, while the 7 steam engines used in the garnet industry aggregated 420 horsepower, and the 7 in the infusorial earth, tripoli, and pumice industry had a total of 410 horsepower. Eighty-eight horsepower was generated by 7 gas or gasoline engines, of which 3, having a capacity of 80 horsepower, were used in the corundum and emery industry, and 4, having 8 horsepower, in the oilstone, whetstone, and scythestone industry. In addition there was 1 electric motor, having a capacity of 5 horsepower; this was used in the infusorial earth, tripoli, and pumice industry.

Production.—The value of the production was $1,177,711, an increase of $541,052 over the value reported for 1889, which was $636,659. Of the particular abrasives, grindstones and pulpstones show the largest increase, $227,844 in value, over the production of 1889. The second largest increase was in oilstones, whetstones, and scythestones, the value of which was $113,968 in 1902, an increase of $80,988.

Oilstones and whetstones are not always finished at the quarries, but are in some instances shipped to a central plant and there prepared for use. When the finishing process is not conducted immediately in connection with the actual quarrying, the value of the crude product is given in Census reports. In the reports of the United States Geological Survey, on the other hand, the finished value is given, for the reason that, with the exception of Arkansas novaculite, this material would not be marketable in its crude state. Were the finished value to be taken in every instance by the Bureau of the Census, the total product for oilstones, whetstones, and scythestones would be increased by $107,794, and the production would rank as second instead of third among abrasive materials.

In order to show comparatively the value of the annual consumption of each abrasive used in the United States, the value of the domestic product and of the imports reported since 1880 are given in the following table. The statistics are compiled from tables of the United States Geological Survey published in "Mineral Resources of the United States."

1902	[6] 1,326,755	426,736	59,808	16,158	104,605	214,842	84,335	132,820	667,431	76,906	55,994	$62,374	221,762	56,456

[1] The value of imports is for fiscal years up to 1886; subsequent years are calendar years.
[2] Figures for imports, and figures for domestic product prior to 1894, not available.
[3] Prior to 1902 no value for pumice is included in these figures.
[4] Figures not available except for 1902.
[5] Value of unfinished product was reported for 1880 and 1889.
[6] Including $107,794 for finisned oilstones, whetstones, and scythestones, and $41,250, the value of quartz, ground, not shown in Census tables.

The value of imports of all abrasives for 1902, $426,736, is 32.2 per cent of the value of the domestic production. The combined value of the domestic production and imports for 1902 was $1,753,491, which is greater than the combined value reported for any other year. In many cases the market value of abrasives is less at the present time than it was ten or twenty years ago, so that the values given represent a greater tonnage now than then.

Of the total value of the imports in 1902, $214,842, or 50.3 per cent, was for corundum and emery, the domestic production of this abrasive being a little less than one-half this value, or only $104,605. The year in which the combined value of the domestic production and imports of corundum and emery was greatest was 1901, when it amounted to $441,039. In that year the value of these imports was greater than during any other year on record, being $294,999, or $80,157 more than in 1902. The year when the value of the domestic production was greatest was 1898, when it amounted to $275,064. The value of the domestic production in 1902, $104,605, was less than that of thirteen of the years recorded. The selling price of corundum and emery varies from 1 to 10 cents per pound.

The class of abrasives ranking next in value of imports is grindstones and pulpstones, for which the imports in 1902 amounted to $76,906, or 18 per cent of the total value of all imports. This is, however, only 11.5 per cent of the total value of the domestic production of grindstones, which was $667,431. A large proportion of the value reported for the imports of grindstones was for pulpstones, from Newcastle-upon-Tyne, England, which are considered to be superior in some respects to those made from the Ohio sandstone. The American stone, however, is giving good satisfaction, which should ultimately cause a decrease in the imports of these pulpstones. The combined value of the imports and domestic production of grindstones and pulpstones was greatest in 1900, when it amounted to $802,607, being $58,270 more than the combined value for 1902, $744,337. The value of the domestic production was greatest in 1900, when it amounted to $710,026, which is $42,595 more than the value of the 1902 production. The next highest value, $700,000, was reached in 1882. It must, however, be taken into consideration that the tonnage of the production during the past ten years was much greater than in 1882, for in that year grindstones were worth about $15 per ton, while now they are sold at from $8 to $10 per ton.

The value of the domestic production of buhrstones and millstones in 1902, $59,808, was greater than that for any year since 1888; while the value of the imports, $16,158, was less than for any year recorded. The combined value of the imports and domestic production in 1902 was $75,966, which is $249,106 less than that of the year of greatest value, 1880, when the figures were $325,072. In that year the value of the imports was also greatest, amounting to $125,072, and the value of the domestic production, $200,000, was only equaled by one other year, 1882. This enormous decrease in the value of buhrstones used in the United States is due largely to the introduction of the roller mill process for grinding wheat. The increase in the domestic production since 1889 is due to the utilization of buhrstones in grinding the coarser cereals, mineral paints, etc., and, as the American stone answers as well for this purpose as the foreign, the continued falling off in the value of the imports is thus partially accounted for.

The combined value of the imports and domestic production of infusorial earth, tripoli, and pumice in 1902 was $118,368, of which $62,374, or over one-half, was the value of the imports. The value of the pumice imported was eight times the value of that produced in this country, while the value of the imports of infusorial earth was only three-fourths the value of the domestic production. It will be noticed that the domestic production of infusorial earth varies very widely from year to year, this being due to its limited use and also to the fact that some producers will mine in one year a quantity sufficient to last them two or more years. The small production of domestic pumice compared to the quantity imported is due to the distance of the domestic deposits from the large markets, which makes it impossible to compete with the pumice imported from the island of Lipari, Italy.

For oilstones, whetstones, and scythestones the combined value of the domestic production and imports for 1902, $278,218, was greater than that for any year since these statistics have been collected. The value of the domestic production for 1902, $221,762, was greater than that of any other year recorded, and was nearly four times the value of the imports for that year of $56,456. The year in which the value of imports was greatest was 1901, when it was $64,655, this being $8,199 more than the value of the imports of 1902. The almost constant increase in the oilstone industry is well illustrated in Table 3. The value of the domestic production has increased from $150,000 in 1891 to $221,762 in 1902. In the same time the imports have increased from $35,344 to $56,456. Prior to 1891 the statistics of the value of the domestic production represented the value of rough, crude rock, while since then it has been principally for the finished oilstone.

There have been no imports recorded of garnet or of crystalline quartz, but in the value of the domestic production of each there has been a general increase. The year of largest production of garnet was in 1901, when the product was valued at $158,100, this being $25,280 more than the value of the production of 1902, $132,820, which was the next highest value recorded. The increase in the value of crystalline quartz used for

abrasive purposes has been very marked, and, with the exception of 1896, the value each year has been greater than that of the year before.

The state in which the greatest value of abrasive materials was produced during 1902 is Ohio, the value being $587,284. The abrasive was principally grindstones, the value of which was $560,412, the balance being oilstones and whetstones. New York was second, with a value of $189,345, the abrasives produced in their order of production being garnet, emery, buhrstones, crystalline quartz, and tripoli.

The detailed statistics of abrasive materials for 1902 are given by states in Table 4 and by classes in Table 5.

DESCRIPTIVE.

The natural abrasive materials can readily be divided into two general groups:

1. Those which occur as rock formation and are cut and manufactured directly into the form desired, while retaining their original rock structure and appearance, as grindstones and whetstones.

2. Those which occur as a constituent of either a rock or a vein, and have to be mechanically separated from the associated gangue and cleaned, as corundum, emery, and garnet.

The artificial products would make a third class of abrasive materials, including carborundum, crushed steel, etc.

The abrasive materials are so universally distributed that there are but few localities where some of them may not be found. While this is the case, various kinds of abrasives are constantly being exported from and imported into the different countries on account either of their superior abrasive efficiency or of their better adaptability to required purposes.

The use of any particular abrasive is dependent upon the character of the abrasion to be accomplished. Thus, while the efficiency of a certain abrasive, as an abrasive, may be greater than that of another, it will not do as satisfactory work as one with less abrasive efficiency. For instance, although corundum has the highest abrasive efficiency of any included in the second type of abrasives mentioned, there are a number of cases where garnet, with a much lower abrasive efficiency, will give better satisfaction.

Grindstones.—The abrasive that is perhaps the most familiar to all is the grindstone. This is produced at the present time in commercial quantities in Michigan, Ohio, and West Virginia, and in much smaller quantities in Montana and Wyoming. The largest quantities are quarried in Ohio, whence the product is shipped to all parts of the United States. The quarries in the northern part of Ohio are located at Chagrin Falls, Berea, Cuyahoga Falls, Elyria, Euclid, Grafton, Independence, Massillon, North Amherst, Oberlin, and Peninsula; those in the eastern part of the state at Empire, Freeport, and Tippecanoe; and those in the southern portion of the state at Amesville, Belpre, Briggsdale, Constitution, Federal, Gravel Bank, Portsmouth, Vincent, and Marietta. A large number of the quarries in northern and southern Ohio have been brought under one management. At Empire, Peninsula, and Tippecanoe the pulpstone variety of grindstone is found; at the quarries at Empire pulpstone is the chief production, the regular grindstone forming but a very small part of the output.

In Michigan there was but one locality in 1902 producing grindstones—that near Grindstone City—but the state ranked next to Ohio in the value of its product.

The quarries in West Virginia are directly across the Ohio river from those in southern Ohio, and are located at Atlantic, Bois, Briscoe, Lonecedar, and Sherman.

Grindstones in very small quantity have been made for local use near Columbus, Yellowstone county, Mont.; near Rawlins, Carbon county, Wyo.; and near Edgemont, S. Dak.; but from the latter locality there was no production in 1902.

There is considerable variation in grindstones, dependent upon the variation of the sandstone from which they are made, which is due (1) to the character of the cementing material—whether it is a hydrous iron oxide, calcium carbonate, or silica; (2) to the percentage of the cementing material—that is, whether the grains are separated from each other by simply a minute film of cementing material or by a considerable layer; (3) to the size and shape of the grains of quartz. According to these variations, there are at least seven grits that are recognized as distinctive, six of which are derived from various grades of Ohio sandstone and one from the Michigan stone. These grits are as follows:

1. The Berea grit, which is a fine, sharp grit, used especially for sharpening edge tools, such as farmers' tools and woodworkers' small tools.

2. The Amherst grit, which is soft and loose, medium and loose, and fine. It is used especially for edge tools, saws, etc., in manufacturing establishments where the grindstone is propelled by steam.

3. The Independence grit, which is a coarse, sharp grit, is used for grinding springs and files and for the dry grinding of castings.

4. The Massillon grit, a coarse, sharp grit, used for grinding large edge tools, springs, files, and castings.

5. The Tippecanoe grit, which is a fairly loose, hard grit, used for grinding wood pulp, springs, files, and heavy forgings.

6. The Marietta grit, which is soft and loose, is used largely in grinding saws, machine knives, and other highly tempered, thin steel tools.

7. The Huron (Michigan) grit is a fine, sharp grit, used for cutlery, mowing machine sections, and tools of that character, where a fine edge is required.

An eighth might be added—the Peninsula grit—a hard and coarse grit, used for grinding wood pulp. In addition to these grades of stone, a grit known as Euclid stone, which contains about 70 per cent of fine silica and 30 per cent of clay, is used for whetters, principally in cutlery works, for polishing out the scratches made by the ordinary grindstone. The production is small, but important.

It may be well to mention here the grades of grindstones that are imported into the United States, as they are used for special purposes for which they seem to be particularly adapted. A grindstone made from a coarse, hard sandstone is imported from Bavaria, and is used particularly for razor grinding. A fine, hard grindstone, called the Craigleith, is imported from Edinburgh, and is used for special purposes in the glass trade.

Although sandstone suitable for the manufacture of grindstones is not uncommon, the variety adapted to the manufacture of a pulpstone is somewhat rare. A considerable demand for pulpstones rose when paper began to be manufactured from wood pulp. In this manufacture a stone is required that can be run in hot water. The Peninsula grit obtained from Peninsula, Tippecanoe, and Empire, Ohio, if carefully selected, ought to make a good pulpstone, which should easily compete with that imported from Newcastle-upon-Tyne, England.

The natural grindstone manufactured from sandstone was formerly in universal use in all kinds of manufacturing plants and in the household, but there has been introduced successfully during the past ten years a grindstone made from emery or corundum. While at the present time only the smaller sized grindstones for household use are made of these materials, it is possible that in the near future large wheels will be made that will rival some of the larger grindstones.

Oilstones, whetstones, and scythestones.—The terms oilstone, whetstone, and scythestone are used somewhat ambiguously, and often the same stone when used for one purpose will be called an oilstone, and when used for another purpose a whetstone, or even a scythestone. The term oilstone has come to be applied to all stones used for sharpening mechanics' tools, for the reason that it is necessary to use oil on most of them to prevent the stone from becoming hot and thus heating the tool, and also to prevent the small particles of steel that are ground off the tools from entering into the pores of the stone.

A considerable change from one census to another is noticeable in the oilstone, whetstone, and scythestone industry in respect to the stone that has the greatest use. While the sale of oilstones and whetstones has increased, or at least held its own, in the United States since 1889, there has been a considerable falling off in the sale of scythestones. This is undoubtedly due to the small number of scythes, sickles, etc., used at the present time, these having been largely replaced by improved agricultural machines and implements. Scythestones are now used in quantity only in those states or countries into which the improved agricultural machines have not yet been introduced. Thus, while the production of scythestones in the United States has remained about the same, it has become necessary to seek a market for them in foreign countries, and a considerable proportion of the production is exported.

The whetstone producing rocks are all sedimentary in origin, and include quartz-mica-schist, sandstone, novaculite, and intermediate rocks. These are found abundantly in various localities, so that there are probably but few countries which have not within their borders a supply of some kind of stone suitable for making whetstones. Although the material for manufacturing whetstones is so common, only those quarries which produce stones of superior quality and have the greatest advantages for manufacturing and shipping can survive the competition in the trade. This is of course the reason the production of whetstones is confined to a few localities. Occasionally a stone is found of exceptional quality, as the novaculite of Arkansas, for which there is a large demand, although the price may be much higher than that of other whetstones. At the present time the domestic supply of whetstones is obtained from Arkansas, Indiana, Ohio, New Hampshire, and Vermont. There is undoubtedly considerable whetstone material utilized in other states, but those mentioned are the only ones that have produced this abrasive for the market.

At the whetstone quarries in Arkansas, which are in Garland and Saline counties, principally at and in the vicinity of Quarry or Whetstone mountain, Garland county, there is obtained the novaculite (sandstone) from which is manufactured the best and most valuable natural oilstone or whetstone on the market. The quality of the rock varies greatly, even in different parts of the same quarry, but two distinct types of stone or grit are recognized, which are known on the market as the Arkansas and Washita. The latter is less dense and much more porous than the Arkansas. Both of these types are divided into two grades, known as soft and hard. They are used principally in the form of small wheels, oilstones of different shapes, and points such as are used by engravers, surgeons, carvers, dentists, jewelers, watchmakers, and diesinkers.

The sandstone of Orange county, Ind., furnishes a whetstone known as the Hindostan or Orange stone, which is quarried in French Lick and Northwest townships. The stone is fine grained and is used for oilstones. It is considered the best low priced sharpening stone for mechanics' tools. A considerable quantity of this stone is now being exported.

At a number of the sandstone quarries in Ohio from which grindstones are obtained, principally at Berea, in Cuyahoga county, and at Grafton, in Lorain county,

a grade of stone is found suitable for whetstones. This stone makes a scythestone that does good work, but it does not stand transportation so well as the scythestone made from schist. At Euclid, Cuyahoga county, is a fine grained sandstone from which a considerable number of oilstones are made. The well-known Deerlick oilstone is made at Chagrin Falls, in the same county, from a fine grained sandstone. Since the introduction of this stone a few years ago its production has increased considerably each year.

In Cortland county, N. Y., near Labrador Lake, a sandstone similar to that quarried in Ohio is found. It is known as Labrador stone, and is used to a limited extent in the manufacture of whetstones, although no product was reported as quarried in 1902.

In Haverhill, Grafton county, N. H., and near Lamoille, Orleans county, Vt., there is a quartz-mica-schist from which are manufactured the celebrated Indian Pond, White Mountain, and Lamoille scythestones. These schists are variable in their structure, so that only portions or bands of them can be utilized. The cutting quality of the stones varies with the compactness of the schists and the percentage of quartz or grit contained. There are two principal grades of stone found at the New Hampshire quarries, which are known as the Indian Pond and the White Mountain. Both of these stones come from the same quarry. The White Mountain is more compact and has a finer texture, and the Indian Pond includes the more laminated varieties of the schist. The name Indian Pond was used as early as 1820 for a stone obtained from a stratum of schist about 7 miles south of Pike Station, near a pond known by the above name. The stones from the quarries at Lamoille are sold under the name of Lamoille stones. At Lisbon, Grafton county, N. H., there occurs a fine grained quartz-mica-schist of a bluish chocolate color, which furnishes a stone known as the chocolate whetstone. It is a medium hard stone and is especially adapted for leather and skinning knives, and it is also used extensively for sharpening cloth cutters' tools, kitchen and carving knives, etc.

Buhrstones and millstones.—The American buhrstone and millstone varies from a sandstone to a quartz conglomerate, which occurs along the eastern slope of the Appalachian mountains, from North Carolina to New York, and is known by different names, according to the locality from which it is obtained. Occasionally a granite is also used in the manufacture of this stone. The states producing buhrstones and millstones in 1902 were New York, North Carolina, Pennsylvania, Vermont, and Virginia, by far the larger production coming from New York. The buhrstone produced in New York is principally from Ulster county, and is known as Esopus stone. The Pennsylvania stones, which are obtained in Lancaster county, are known as Turkey Hill and Cocalico. From Montgomery county, Va., is obtained a buhrstone which is known on the market as Brush mountain stone. In Rowan county, N. C., a granite is quarried and manufactured into millstones, which are sold, for the most part, in North Carolina and Georgia.

Whereas formerly a large number of buhrstones were used in the United States, principally in grinding wheat, now very few are used for that purpose on account of the introduction of the roller mill process. Buhrstones are still used for this purpose only in certain mountain districts where railroad facilities are wanting. New uses, however, have arisen for these stones, and they are now employed quite extensively for grinding the coarser cereals, mineral paint ores, fertilizers, cement rock, barytes, and other minerals. For these purposes the use is increasing each year, although at the census of 1902 the value of the buhrstones produced was only about one-sixth of the value of those reported at the census of 1880. The decided change in this industry began in 1888, and there was a gradual falling off until 1894, when the industry again began to improve with the introduction of the new uses for the stone.

Garnet.—The greater part of the garnet that is mined for abrasive purposes, except the production from North Carolina, is used in the manufacture of garnet paper, which is extensively employed for abrasive purposes in the manufacture of boots and shoes. Nearly all the production from North Carolina is manufactured into wheels, which are sold as emery wheels. The abrasive value of garnet was known to the North American Indians, who engraved shells with tools consisting of garnet points attached to wooden handles.[1]

During 1902 garnet was obtained from Connecticut, New York, North Carolina, and Pennsylvania.

In Connecticut, near Roxbury, Litchfield county, garnet is obtained from a mica-schist, in which it occurs in crystals from less than a quarter of an inch to nearly two inches in diameter. As the rock is crushed, the crystals readily separate from the schist, making a clean garnet concentrate, that is ready for crushing and sizing.

The principal New York garnet localities are near North river, in Warren county, and in Essex county. The mineral occurs in segregated masses, in both gneiss and limestone rocks, varying in size from that of a pigeon's egg to a diameter of 20 feet. Commercially, this garnet is designated (1) as massive garnet, when it is in the larger masses, which are impure; (2) as shell garnet, which is nearly pure garnet; and (3) pocket garnet, when it occurs in small masses or crystals in the gneiss. Of these, the shell garnet is considered the most valuable.

The North Carolina garnet deposits that have been developed are all in Jackson county. The principal mine is on Sugar Loaf mountain, about one and one-half miles from the railroad. The occurrences are all similar, being bands of garnetiferous gneiss in ordinary

[1] United States Geological Survey, Twelfth Annual Report, Part VI, 1889, page 608.

gneiss. These bands are 50 or more feet in width, and average from 15 to 30 per cent of garnet.

In Delaware and Chester counties, Pa., a garnet occurs in small crystals and fragments thickly disseminated through a gneiss which is badly decomposed. A considerable product, reported from Delaware county, is known on the market as rose garnet.

Crystalline quartz.—The production of crystalline quartz that is included under the head of abrasives, is that which is used in the manufacture of sandpaper, scouring soaps, and as a wood finisher. In addition to these uses there are large quantities of quartz sand used in the stonecutting trade, especially by the marble workers. A small amount of quartz is pulverized, and sold under the name of tripoli. Of the production reported for 1902 the larger amount was used as a wood finisher, and was obtained from Connecticut. Most of that used in the manufacture of sandpaper was mined in Pennsylvania.

Infusorial earth and tripoli.—Among the abrasives, infusorial earth and tripoli formed but a small proportion of the production, and of the amount produced less than half was actually used for abrasive purposes. Under the head of infusorial earth and tripoli are included all porous, siliceous earths of organic origin, such as infusorial earth, diatomaceous earth and tripoli, and also a siliceous material which is the residue from an impure siliceous limestone by the leaching out of the calcium carbonate. The material produced in 1902 was from California, Georgia, Maryland, Missouri, New Hampshire, New York, and Virginia.

Pumice.—The production of pumice in the United States has been very erratic during the time for which statistics of this material have been published, although commercial deposits are known to occur in large quantity, especially in Utah and Nebraska. On account, however, of the distance of these deposits from the railroad, and from the large markets, they are not able to compete with the pumice imported from Lipari, Italy, which is shipped largely as ballast, and which, after being ground and bolted, is sold in New York at from 2 to 2½ cents per pound. These Lipari deposits supply almost the entire demand for pumice. During 1902 the entire production of pumice in the United States was from the Nebraska deposits, and was used largely in the manufacture of soaps and scouring powders.

Corundum and emery.—The natural abrasives that have the highest abrasive efficiency are corundum and emery, and there is an increasing demand for these, which is due largely to the increase in manufacturing, especially of agricultural machines, but also to the improved methods that have been devised for making emery and corundum stones and wheels of all shapes and sizes. These abrasives, manufactured into wheels of various sizes, have replaced, to some extent, the smaller grindstones in manufacturing establishments. They have also been manufactured into oilstones and whetstones, and have successfully competed with the natural product, although selling at a higher price. With the exception of certain emery wheels made by the silicate process, and used for saw gummers, no large emery wheels have as yet been made. Even if large vitrified emery wheels could be made, it is a question whether their cost could be lowered sufficiently to permit them to enter into competition with the grindstone, and also whether the emery stone would do as satisfactory work as the grindstone for certain kinds of grinding.

Of the corundum and emery used in the United States about one-half is produced in this country, the remainder being obtained from the Turkish and Grecian emery mines, and from the Canadian corundum mines. There were but a few tons of corundum produced in the United States in 1902, the production of this type of abrasives being almost entirely of the emery variety. Corundum was formerly regarded as occurring sparingly in nature, but it is now known to have a rather wide occurrence and to exist in commercial quantity in many localities. With the known occurrences of this mineral in this country there should be no difficulty in such production of it as to fully satisfy the markets' demand. Competition with the Canadian corundum will be strong, and if there is a decrease in price, the location of the deposits for easy mining and sufficient railroad facilities will need to be very favorable if they are to be profitably worked. The value of corundum in 1902 was from 7 to 10 cents per pound when cleaned and sized. Emeries varied in price from 1 to 5 cents per pound.

The more promising deposits of corundum in the United States are as follows: In North Carolina, at Corundum Hill, Macon county; at Sapphire, Jackson county; and at Brick creek, Clay county. In Georgia, at Laurel creek, Rabun county; and in Montana, on the headwaters of Elk creek, Gallatin county. The emery deposits are near Peekskill, N. Y., and at Chester, Mass., the latter furnishing the most of the emery produced in the United States. During 1902 there was also a small production in Montana.

TABLE 4.—DETAILED SUMMARY, BY STATES: 1902.

	United States.	Arkansas.	Connecticut.	Indiana.	New York.	Ohio.	Pennsylvania.	Virginia.	All other states.[1]

BORAX

BORAX.

By Joseph Struthers, Ph. D.

The first commercial production of borax in the United States was in 1864, when 12 short tons were mined in California. Since that year the production has fluctuated from nothing in 1869, 1870, and 1871, to 19,142 short tons in 1902. Up to the present investigation borax has never been separately treated in the census of mines and mining. Table 1 is a summary of the statistics for 1902.

Table 1.—*Summary: 1902.*

Number of mines or quarries	6
Number of operators	6
Salaried officials, clerks, etc.:	
Number	14
Salaries	$18,128
Wage-earners:	
Average number	153
Wages	$114,865
Miscellaneous expenses	$47,606
Cost of supplies and materials	$213,538
Product:[1]	
Quantity, short tons	19,142
Value	$2,383,614

[1] The United States Geological Survey reports 20,004 short tons, valued at $2,538,614, which includes 862 short tons of boric acid, valued at $155,000. This acid, representing a manufacture, is not reported by the Census.

There were only 6 productive mines or quarries in 1902, and these were not widely separated geographically. Four were in California, and 1 each in Nevada and Oregon. Each company operated a single mine only. An average of about 25 wage-earners for each mine is shown. For the industry as a whole a total average for the year of only 167 salaried employees and wage-earners is reported. Compared with the amount paid in wages and salaries and for miscellaneous expenses, the cost of supplies and materials appears large.

Six mines were idle in 1902—3 in California, 2 in Nevada, and 1 in Oregon—and at 1 mine in California development work was carried on.

Capital stock of incorporated companies.—Every active company reported was organized as a corporation. Their capitalization appears in Table 2.

Table 2.—*Capitalization of incorporated companies: 1902.*

Number of incorporated companies	6
Capital stock:	
Total authorized—	
Number of shares	823,750
Par value	$3,175,000
Total issued—	
Number of shares	822,250
Par value	$3,025,000
Dividends paid	$231,600
Common—	
Authorized—	
Number of shares	573,750
Par value	$2,925,000
Issued—	
Number of shares	572,250
Par value	$2,775,000
Dividends paid	$231,600
Preferred—	
Authorized—	
Number of shares	250,000
Par value	$250,000
Issued—	
Number of shares	250,000
Par value	$250,000

These companies, as a rule, refine the crude borax, and it must be remembered that the capitalization shown includes that utilized for the equipment and maintenance of the refining plants. Refining, however, is too closely related to mining to allow of satisfactory segregation.

The par value of the total amount of capital stock authorized for these companies was $3,175,000, representing 823,750 shares of both common and preferred stock. Shares to the number of 822,250, with a par value of $3,025,000, were issued. Of these 572,250 shares were of common stock with a par value of $2,775,000, and 250,000 shares were of preferred stock with a par value of $250,000. All the preferred stock authorized was issued, as was all but 1,500 shares of the common stock. There was paid $231,600 in dividends on the common stock issued. This is equivalent to 8.35 per cent on its par value. No dividend was paid upon the preferred stock. There was no bonded indebtedness.

Employees and wages.—The average number of wage-earners employed during each month of 1902, and the

daily rates of pay, are shown in Table 6. The importance of this industry is not to be judged by the number of men to whom it gave employment, only 174 at the maximum, during the cool months of the year. In summer, from June until September, the heat in the southeastern counties of California does not permit active operations, which as a consequence are reduced to a minimum. On the coming of cooler weather, however, operations are at once resumed, as appears from the number of men reported employed in September and October.

Here relatively high rates of pay are shown. Fifty per cent of the engineers received from $3.25 to $3.49 per diem; 3 of the 6 mechanics got above $3.50 per diem. Over 71 per cent of those classed as miners or quarrymen received from $2.50 to $3.24 per diem. All of the miners' helpers received from $2.50 to $2.74. Of "all other wage-earners" none was paid less than $1.50 per diem, and more than two-thirds, or 67.4 per cent, received from $2 to $3.24.

Mechanical power.—Mechanical power to the amount of 338 horsepower was reported. Two hundred and five horsepower were furnished by 5 steam engines, 123 horsepower by 11 gas or gasoline engines, and 10 horsepower by 1 water wheel. There was also 1 electric motor of 1 horsepower.

Production.—Table 3 shows the annual production of borax in California from 1889 to 1902, as reported by the United States Geological Survey.

TABLE 3.—*Production of borax in California: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

YEAR.	Quantity (short tons).	Value.
1889	965	$145,473
1890	3,201	480,152
1891	4,267	640,000
1892	5,525	838,787
1893	3,955	593,292
1894	5,770	807,807
1895	5,959	595,900
1896	6,754	675,400
1897	8,000	1,080,000
1898	8,300	1,153,000
1899	20,357	1,139,882
1900	25,837	1,013,251
1901	23,231	1,012,118
1902[1]	20,004	2,538,614

[1] Includes small quantities and value of same, mined in Oregon and Nevada. To separate would reveal the operations of single operators.

Since 1864, when the first production was reported, 156,354 short tons of borax have been produced in California. This is practically the production for the whole United States. Prior to 1890 the number of short tons produced annually had passed the thousand mark only in 1875, 1876, 1884, 1886, 1887, and 1888. In 1889 the production sank slightly below this mark, only to rise with a bound in 1890 to 3,201 tons, the greatest up to that time. From then until 1900, with the exception of 1893 when there was a temporary setback, it gradually increased to 25,837 tons. In 1901 a production of 23,231 tons was reported, and in 1902, 19,142 tons, exclusive of the 862 tons of boric acid reported by the Geological Survey. The decrease in output for these years is apparent only, for it must be borne in mind that the figures of production are for both crude and refined, and that the proportions of each may vary greatly each year. The tendency of late years has been to do as much refining or concentrating as is possible at the place of production. Thus in 1902, while 43,010 short tons of crude ore were mined, 40,410 tons of this received some treatment at the mines, making 16,542 tons of refined product, which, with the remaining 2,600 tons of crude, comprise the 19,142 tons reported.

Table 4 gives the production of borax and boron compounds in the principal producing countries of the world from 1896 to 1901, inclusive, as reported by the United States Geological Survey.

TABLE 4.—*The production of borax, borates, etc., in the principal countries of the world: 1896 to 1901.*[1]

[1] From official reports of the respective countries, except the United States.
[2] Exports.
[3] Fiscal years.
[4] Total exports, 1897 to 1901, amounted to 43,851 tons, valued at £789,318.
[5] Statistics not yet available.

The control of the borax industry in the world is now practically in the hands of the Borax Consolidated (Limited), an international trade combination which was formed in 1898 with a capital stock of £1,400,000 to acquire all the important borax-producing properties in the world. This concern owns or controls borax lands and refineries in the United States, England, France, Chile, Peru, and Turkey.

The future of the borax industry indicates an increased demand for borax and boric acid, as well as an increase in the number of industrial purposes to which these and their compounds are applicable. At the present time the various industries in which boron compounds are used include the manufacture of earthen, china, and glass ware, enameled ironware, smelting, tanning, calico printing, cement making, color manufacture, bleaching, soapmaking, and meat packing. Boron compounds are also used in laundries and for many household, toilet, and surgical purposes.

There has been considerable discussion as to the use of boric acid as a preservative for food, and the preponderance of the evidence seems to be in favor of its employment in small quantities as an entirely harmless preservative, but only a small proportion of the total supply in the world is utilized for this purpose.

In order to provide data from which may be calculated an estimate of the consumption of borax and boron salts in the United States, Table 5, showing the imports, has been prepared by the United States Geological Survey from the reports of the United States Treasury Department.

A detailed summary showing the statistics for borax during 1902 is given in Table 6.

DESCRIPTIVE.

Historical.—The occurrence of borax in the United States was discovered in California by Dr. John A. Veatch, January 8, 1856. Having boiled a small quantity of water from Lick Spring (then known as Tuscan Spring), Doctor Veatch noticed that, as the water cooled, crystals formed and adhered to the sides of the vessel. These crystals proved later to be sodium biborate, or borax. Shortly afterwards Doctor Veatch found small quantities of borax at the mouth of the Pitt river, in Shasta county, and traces of this salt in numerous springs in the Coast Range mountains; but it was not until September, 1856, that he discovered the extensive marsh deposits on the eastern side of Clear Lake, in Lake county, which subsequently furnished a large share of the borax produced in the United States.

The year 1864 witnessed the beginning of the borax industry in this country. In that year 12 short tons (24,304 pounds) of borax were obtained by evaporating the saline waters from Borax Lake, adjacent to and connected with Clear Lake, in Lake county, 80 miles north of San Francisco. Later the waters of the lake were enriched by the addition of crystalline borax collected from the alkaline marshes surrounding the lake.

Until the early seventies, the output of borax in California was obtained solely from the waters of Clear Lake and other lakes in the state, but after that time the discovery of large quantities of pure borax in many of the alkaline marshes in eastern California and western Nevada, caused the abandonment of the lake refineries and the erection of new plants, notably near Columbus, Nev.; at Searles marsh in the Amargosa valley; and at the mouth of Furnace creek in Death Valley, California. Despite the difficulty and great cost of transporting the refined product by teams 100 miles to the railroad, the refineries continued in successful operation for several years, until the relatively large increase in the domestic output, together with the increased imports from Italy, so reduced the price that the working of the marsh deposits became no longer profitable and the refineries were closed down. About the year 1890 it was found that the borax crust on many of the marshes had been formed by the leachings of beds of calcium borate (borate of lime) in the Tertiary lake sediments in that region. Owing to the large extent of these bedded deposits, which possessed also the double advantage of containing a purer grade of mineral and of being more easily accessible than the marsh deposits, the borax industry as it existed at that time was revolutionized. A mine was started on a bedded deposit of from 6 to 10 feet in thickness at Borate, 12 miles northeast of Daggett, Cal., in San Bernardino county, and a refining plant was erected by the Pacific Coast Borax Company. This company was organized in 1888, and at the present time is the chief producer of borax in the United States, as well as the producer of a large part of the output of boric acid. The ore at Borate consists of colemanite (a calcium borate mineral) in large masses more or less connected by stringers and bands in a bedded deposit of from 5 to 30 feet in thickness, interstratified in lake sediments. The great value of this deposit led to extensive prospecting in other parts of the state, which has resulted in the discovery in Death Valley of enormous quantities of colemanite reported to exceed greatly in value the deposit at Borate. Both at Borate and in Death Valley the deposits are of similar occurrence, being contained in a regular stratum interbedded with semi-indurated sands and clays which comprise the bulk of the strata. These beds are regarded as of Tertiary age, and are supposed to have been deposited from inclosed bodies of water. Large plants for the concentration and refining of the crude ore have been erected in California: At Alameda, near San Francisco (inoperative during 1902), at Marion, and at Daggett. The largest borax refinery in the United States, however, is at Bayonne, New Jersey.

Review of the borax industry during 1902.—There were 4 companies engaged in the borax industry in California during 1902—the Pacific Coast Borax Company, the American Borax Company, the Western Borax Works, and the Frazier Borate Mining Company. The Pacific Coast Borax Company, continued to supply a sufficient quantity of borax to satisfy the requirements

of the market; and apart from its operations at Borate, prospecting work for other colemanite deposits has been carried on in Death Valley and much additional property has been acquired. The deposits in Amargosa Valley were carefully examined and large sample lots of ore were transported by traction engines to Manville, 100 miles distant, and thence by rail to the refinery for testing the quality, in order to determine the value of the property. The large borax refinery at Bayonne, N. J., was destroyed by fire in April, 1902, but has since been entirely rebuilt.

The American Borax Company, is under the control of the Standard Sanitary Company, of Pittsburg, Pa. The plant of this concern at Daggett has been greatly extended by the addition of two 20,000-gallon tanks or digesters for the treatment of the crude material from the adjacent mud deposits by the sulphuric acid process, which is referred to in detail later in this report. The enlargement of this plant has greatly increased the output of boric acid concentrates, and the results have been so satisfactory that a further extension of the plant at Daggett is contemplated. A new refinery is in course of erection at Pittsburg, to which will be shipped the concentrates from Daggett for the final refining.

The mines of the Western Borax Works are located in Inyo county, and those of the Frazier Borate Mining Company in San Bernardino county.

Apart from the output of the above-named concerns, a small quantity of borax has been obtained from the marsh deposits in California and Nevada, but the total amount produced from these scattered sources has been of so little comparative importance that the borax market was in no way affected. During the past few years Oregon has contributed to the domestic supply a small quantity of borax from the marsh deposits in Harney county. The output has averaged about 400 tons annually except in 1902, when 120 tons were reported, as the mining operations had given way greatly to development work. The chief borax producer in this state is the Rose Valley Borax Company, controlling 2,000 acres of rich marsh land near Lake Alvord in the southeastern part of Harney county. The total area of the deposit, which is south of the lake, aggregates approximately 10,000 acres. The ground is level and treeless, and is incrusted with a layer several inches thick containing in addition to sodium borate numerous other salts of sodium. During the long summer months the loose surface deposit is shoveled into small heaps, and is subsequently replaced with a second incrustation within a comparatively short period of time. The stock of crude material collected during the summer is sufficient to enable the refinery to continue in operation throughout the entire year. The crude mineral, containing from 5 to 20 per cent of boric acid in combination with a sodium base, is shoveled into tanks containing boiling water to which is added a proper quantity of chlorine gas or sulphuric acid to decompose the alkali salts and thus liberate the boric acid. After a treatment of twenty-four hours in the tank the clear supernatant liquor is withdrawn to the crystallizing vats and allowed to cool, which causes the boric acid to separate in the form of crystals, leaving a mother liquor, which is used repeatedly until it contains sufficient sodium salts to warrant a separate treatment.

Occurrence.—The principal minerals containing boron are as follows: Sassolite, boric acid (H_3BO_3); borax (tincal), sodium biborate ($Na_2B_4O_7.10H_2O$); ulexite (boronatrocalcite) ($CaNaB_5O_9.8H_2O$); colemanite (impure varieties, priceite and pandermite), calcium borate ($Ca_2B_6O_{11}.5H_2O$); and boracite (stassfurtite), magnesium borate ($2Mg_3B_8O_{15}.MgCl_2$). Boron is also a constituent of several common silicate minerals, notably tourmaline and datolite. Borax, sodium biborate ($Na_2B_4O_7.10H_2O$), is the only important salt derived from boric acid. It occurs native in California, Ceylon, and Thibet, and from the last-named place it is obtained in the form of tincal, an impure crystallized borax containing calcium and magnesium sulphates and chlorides and a greasy substance which is added presumably to protect the crystals from efflorescence and breakage. The tincal is purified by dissolving in warm water and adding limewater and calcium chloride in order to precipitate the grease as a lime soap. After filtering, the pure crystals of boric acid are obtained by evaporating the solution.

Physical and chemical characteristics.—Several forms of borax are used in industrial, medicinal, and laboratory processes—the principal one being prismatic sodium borate (borax, $Na_2B_4O_7.10H_2O$). There is a second variety called "octahedral borax" which contains five molecules of water of crystallization ($Na_2B_4O_7.5H_2O$), forming octahedral crystals. The latter variety, unlike prismatic borax, becomes opaque upon exposure to moist air and is converted by the absorption of water into the prismatic form.

A property of molten borax of great utility in analytical research is that of dissolving various metallic oxides, thereby forming transparent glasses of characteristic colors. By making a borax bead on a loop of platinum wire held in a blowpipe flame, and dissolving therein the substance under examination, the presence of certain metals is easily distinguished.

Borax is also of great value in assaying gold and silver ores, being used to dissolve and remove the base metals from the metallic lead button containing the gold and silver of the sample of ore tested. This property of dissolving oxides is utilized also in soldering and brazing metals that are oxidizable by heat; the molten borax absorbing any oxides formed whose presence mechanically would prevent the close adhesion of the metals so necessary for a proper weld or soldered joint.

Among other important uses are as a constituent of strass or paste for making glass and enamels; as a glaze

for fine earthenware; in combination with shellac as a varnish for stiffening felt hats; with casein as a substitute for gum arabic, and (on account of its antiseptic qualities) as a household soap; as an ingredient of various cosmetics; and as a solution for cleansing the hair.

Boric acid (H_3BO_3) (old name boracic acid): In Tuscany the vapors escaping from the hot springs and from openings in the ground (fumaroles) contain boric acid, and in some places this substance is obtained as crystals by the evaporation of water from these fumaroles. The crystals or crusts produced naturally form the mineral sassolite. The crystals of boric acid are white in color, laminated in structure, and possess a mother-of-pearl luster. They dissolve readily in hot water though very slightly in cold. Upon being heated to 160° C. they lose one-half the water of crystallization and become transformed to pyroboric acid ($H_2B_4O_7$). At a red heat all of the water is expelled and boric anhydride (B_2O_3) results, which, even at high temperatures is stable and nonvolatile, and for this reason it is able to decompose nearly all of the metallic sulphates, forming when fused with them, metallic borates.

Fused boric anhydride when cold resembles ordinary glass in transparency, hardness, and brittleness. The chief uses of boric acid are in the manufacture of borax; in making colored glazes for the decoration of iron, steel, and other metallic objects; in enamels and glazes for pottery; in the manufacture of flint glass and strass or paste from which artificial stones are cut; in making Guignet's green; as an antiseptic in medicine and surgery; and as a preservative for fish, meat, milk, and other foods.

The principal methods used in the manufacture of boric acid are thus described:

The chlorine or Moore process.—In this process, which is used to some extent in England, the crude colemanite in powdered form is suspended in water and heated to 70° C.; then chlorine gas is passed into the liquor and reacts on the colemanite, forming boric acid, calcium chloride, and calcium chlorate. The greater part of the boric acid crystallizes out upon cooling and is subsequently purified by repeated crystallizations. The residue solution, called mother liquor, is used many times until the accumulated calcium salts begin to separate out in the form of crystals.

The hydrochloric acid process.—The mode of procedure in this process is as follows: Two parts by weight of hydrochloric acid and four parts of water (the volume of the latter being kept constant) are used, in which the calcium borate is boiled until dissolved. The boric acid is then crystallized out of the cooled liquor, leaving the calcium chloride still in solution. Before the crystals are in proper condition for packing and shipping, an additional treatment is necessary, which consists of draining, "whizzing," and washing with cold water, concluding with a second and final "whizzing." In Germany the hydrochloric acid process is used to extract the boric acid from the boracite contained in the famous Stassfurt salt deposits. The material is crushed and treated with hydrochloric acid, the resultant pasty mass is dissolved in boiling water and the solid material separated and removed by filtration or decantation; the clear solution is then crystallized in iron tanks, yielding pure crystals of boric acid. The chemical reaction involved is $(2Mg_3B_8O_{15}), MgCl_2 + 12HCl + 18H_2O = 7MgCl_2 + 16H_3BO_3$.

The sulphuric acid process.—In this process calcium borate is treated with sulphuric acid, the reaction yielding soluble boric acid and precipitated calcium sulphate. The boric acid is obtained by leaching with hot water, the solution so produced being concentrated by evaporation until the crystals of boric acid separate out from the solution. In California the process is slightly modified. The borate mud is boiled in huge tanks with water containing sulphurous acid, which decomposes the calcium borate, thereby liberating the boric acid in the solution and leaving the calcium in the form of insoluble calcium sulphate. As before, the boric acid is dissolved by leaching with hot water, which, however, extracts also a small quantity of other soluble salts. For this reason fractional crystallization is necessary in order to obtain a fairly pure product. In a few works the insoluble calcium sulphate is separated and removed by passing the muddy solution from the tanks through filter presses.

The sulphuric acid process is sometimes used to decompose the boracite of the Stassfurt deposits, and in this case Epsom salt is obtained as a by-product from the magnesium sulphate contained in the mother liquor, according to the following chemical reaction: $(2Mg_3B_8O_{15}), MgCl_2 + 7H_2SO_4 + 18H_2O = 7MgSO_4 + 2HCl + 16H_3BO_3$.

The ammonia process or bigot process.—Boric acid is produced by heating in a closed vessel 100 parts of colemanite and 150 parts of ammonium sulphate. The product of the first reaction is ammonium borate, which is later decomposed into ammonia and boric acid. The ammonia is condensed and collected, and the boric acid is dissolved from the residuum by leaching with water and concentrating the resultant aqueous solution until crystals of boric acid are formed. The crystals are then removed, washed with water until free from adhering mother liquor, dried, and packed for shipment to the market. At times the crystals are ground to a fine powder before being packed and shipped.

The manufacture of borax from boric acid.—The process generally used to make borax from boric acid is briefly summarized as follows: Equal quantities of crystallized sodium carbonate and water are heated by steam in a lead-lined vessel, and to the solution thus obtained sufficient boric acid is gradually added to combine with the sodium carbonate and form the borax salt $(Na_2B_4O_7), 10H_2O$. Another process is to prepare solu-

tions of ammonia, sodium nitrate, and boric acid in the proportions of two, one, and two, respectively. By heating this mixture and dissolving in water, borax and ammonium nitrate are formed. In both of these cases the crystals of borax are ultimately obtained by the evaporation of the solutions containing the borax salt.

The manufacture of borax from colemanite.—At the borax refinery in Alameda, Cal., the process used to convert colemanite into borax crystals is briefly outlined as follows: The crude colemanite, obtained direct from the mines, is first broken into lumps of from three-fourths to 1½ inches in diameter, then reduced in a grinding mill to the size of fine sand, and finally passed through rolls which grind the material to the fineness of flour. The floured product is transferred to an iron tank partly filled with water containing in solution the proper proportion of sodium carbonate necessary to decompose the calcium borate. (A ready and cheap supply of sodium carbonate is obtained from Owens Lake, Cal.) Heat is applied to the tank and the contents boiled and thoroughly agitated by means of a mechanical agitator. After a short time the chemical reaction has become completed, the double decomposition being the change from calcium borate and sodium carbonate to calcium carbonate and sodium borate. The sodium borate being soluble is extracted from the insoluble calcium carbonate by leaching with hot water, which dissolves in addition a small quantity of other soluble salts from the impurities in the ore and sodium carbonate. As a consequence the crystals of borax obtained by cooling and evaporating this solution in tanks are of a dark color and somewhat impure. They are purified by a second solution in hot water and a second crystallization in a special vat having a series of suspended wires on which the purer borax crystals form. The crystals on the sides and bottom of the vat are less pure. The purified crystals of borax are removed from the vats, washed free from adhering mother liquor, dried, ground, and screened into several grades for the market.

At the Marion (Cal.) works the crude colemanite ore is submitted to a concentration, and the rich concentrates are shipped to the refinery at Bayonne, N. J., for final conversion into borax. These concentrates are in two forms, lumps and fines. Formerly the low grade ores at Marion were rejected, but at the present time they are heated in a two-hearth, 100-ton Holthoff-Wethey furnace, fired by six oil burners. A gentle heat suffices to cause the colemanite in the ore to disintegrate physically into a sand-like product called "flour," which is removed when cold by screening, and is sacked and shipped to the Bayonne refinery. One disadvantage of the separation of the colemanite by heating in a furnace is that any pandermite (the compact variety of the mineral) present in the ore is not affected by the heat, and is consequently left in the waste material remaining in the screens. At times the waste equals in quantity one-half of the "flour" product.

The conversion of the colemanite into borax at the Bayonne refinery in New Jersey is made by decomposing the calcium borate with sodium carbonate, leaching out the sodium biborate with water, yielding a solution which is separated from the insoluble calcium carbonate by passage through a filter press at a pressure of from 50 to 100 pounds per square inch. The clarified solution is transferred to vats having wires suspended from 2-inch iron pipes extending across the top of the vat. The crystals of borax form on these wires as well as on the sides and bottom of the vat, those on the wires being sufficiently pure for all trade requirements, while those on the sides and bottom of the vat have to be redissolved and purified by a second crystallization. The pure crystals are crushed, screened, and sorted into three grades—refined crystals, refined screenings, and granulated borax. The crystals and screenings are packed for the market, but the granulated borax before shipment undergoes a final treatment, which consists of heating in an inclined rotating cylindrical furnace, crushing to the fineness of flour in a pulverizer, settling and collecting the dust in a large dust chamber, and packing the final product for market. The Bayonne refinery is well equipped with all modern mechanical devices for the handling and treatment of the crude and finished materials.

TABLE 6.—*Detailed summary: 1902.*

Number of mines or quarries	6

FLUORSPAR

FLUORSPAR.

By Joseph Hyde Pratt.

The mining of fluorspar has increased very greatly since the census of 1890, due to the large increase in the use of this mineral in metallurgical processes, especially in the iron industry. For some years the use of fluorspar for fluxing iron was not large, because it was feared a constant supply could not be obtained. At that time the mineral was produced in only one state, Illinois, although it was known to occur in small quantity in a number of other states. Now, however, it has been proved to occur in commercial quantity in Arizona, Illinois, Kentucky, and Tennessee.

The first census statistics for fluorspar were collected at the Eleventh Census, and these are compared with the statistics for 1902 in the following table:

Table 1.—*Comparative summary: 1902 and 1889.*

	1902	1889
Number of mines	22	(1)
Number of operators	18	(1)
Salaried officials, clerks, etc.:		
Number	42	(1)
Salaries	$27,311	(1)
Wage-earners:		
Average number	269	101
Wages	$110,002	$14,213
Contract work	$300	(1)
Miscellaneous expenses	$23,602	$3,008
Cost of supplies and materials	$31,374	$5,025
Product:[2]		
Quantity, short tons	48,818	9,500
Value	$275,682	$45,855

[1] Not reported.
[2] The United States Geological Survey reports 48,018 short tons, valued at $271,832, which is the product marketed. Census figures represent the product mined.

Less than one-tenth of the total quantity and about one-fifth of the entire value reported for 1902 represent the product prepared at the mine for the market, the preparation consisting of drying and grinding, in addition to the usual washing.

Of the 22 mines in 1902, 14 were in Kentucky, 5 in Illinois, 2 in Arizona, and 1 in Tennessee. The product has increased from 9,500 tons in 1889 to 48,818 tons in 1902, or over fivefold, and the value from $45,835 to $275,682, or over sixfold. In these twelve years, Illinois, which was the only state producing fluorspar commercially in 1889, has increased its production from 9,500 tons, valued at $45,835, to 18,860 tons, valued at $123,000, or 98.5 per cent in amount and 168.4 per cent in value. One mine in Kentucky was reported idle in 1902. At two mines in Illinois development work was done, and the statistics for these are shown in the following statement:

Development work: 1902.

Number of mines	2
Number of operators	2
Wage-earners:	
Average number	5
Wages	$2,125
Cost of supplies and materials	$2,800
Miscellaneous expenses	$25

The 22 productive mines were controlled by 18 operators—2 individuals, 2 firms, and 14 incorporated companies.

Capital stock of incorporated companies.—The details of the capital stock and funded debt authorized and issued by the 14 incorporated companies are shown by states in Table 2.

Table 2.—*Capitalization of incorporated companies: 1902.*

	United States.	Illinois.	Kentucky.	All other states.[1]
Number of incorporated companies	14	3	9	2
Capital stock and bonds issued	$2,214,000	$1,536,000	$628,000	$50,000
Capital stock (all common):				
Total authorized—				
Number of shares	3,146,730	2,500,000	606,630	40,100
Par value	$3,813,000	$2,500,000	$1,263,000	$50,000
Total issued—				
Number of shares	1,726,320	1,536,000	150,220	40,100
Par value	$2,154,000	$1,536,000	$568,000	$50,000
Bonds:				
Authorized—				
Number	1,000	.....	1,000	.....
Par value	$100,000	.....	$100,000	.....
Issued—				
Number	600	.....	600	.....
Par value	$60,000	.....	$60,000	.....

[1] Includes companies distributed as follows: Arizona, 1; Tennessee, 1.

The 9 Kentucky companies issued capital stock to the amount of $568,000 and bonds to the amount of $60,000, making a total of $628,000, which is equivalent to 28.4 per cent of the total capitalization of all companies. The 3 companies in Illinois issued $1,536,000 of capital stock, representing 69.4 of the total capitalization. No dividends were reported on any of the stock and no interest was paid on the bonds.

Employees and wages.—The salaried employees numbered 42, or 13.5 per cent of the 311 salaried employees and wage-earners, and their salaries were $27,311, or 19.9 per cent of the total salaries and wages, which amounted to $137,313. The 269 wage-earners, there-

fore, constituted 86.5 per cent of the total number of employees, and their wages 80.1 per cent of the total salaries and wages.

As shown in Table 4, the busiest months in this industry, all states combined, were from May to December, inclusive. In Illinois, the largest number was employed in August; in Kentucky the maximum was not reached until October, which was true also of "all other states." The average number of wage-earners, at specified daily rates of pay for the different occupations is shown in Table 4. The majority of the miners received from $1.25 to $1.49 per day, 100 miners, or 56.8 per cent of the total number, receiving wages within these limits. For 35 miners, or 19.9 per cent of the total number, the wages were lower, being between $1 and $1.24 per day, while for 41 miners, or 23.3 per cent of the total number, they were higher, 32 miners receiving between $1.50 and $1.74, 5 between $1.75 and $1.99, and 4 between $2 and $2.24. Of the 16 engineers reported in the industry, 14 received between $1.50 and $1.74, and 2 received between $2.50 and $2.74. The rates paid machinists and engineers were, on the whole, higher than those for other wage-earners. The employees at the higher rates, included under "all other wage-earners," are men who wash or jig the ore.

Supplies, materials, and miscellaneous expenses.—The cost of supplies and materials amounted to $31,374, and the miscellaneous expenses were $23,602. The amount included in the latter item for payment of royalties and rent of mines and mining plants was $7,900, or 33.5 per cent of the total; the balance, $15,702, or 66.5 per cent, was paid for rent of offices, taxes, insurance, interest, and other sundries.

Mechanical power.—At the 22 mines, primary power was employed aggregating 669 horsepower, of which 530 or 79.2 per cent was steam, and 139 or 20.8 per cent, gas or gasoline. There was, in addition, one electric motor, with a capacity of 25 horsepower.

Production.—The following table shows the quantity and value of fluorspar produced and sold since 1882:

TABLE 3.—*Production of fluorspar: 1882 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

YEAR.	Quantity (short tons).	Value.	Average value.	YEAR.	Quantity (short tons).	Value.	Average value.
1882	4,000	$20,000	$5.00	1893	12,400	$84,000	$6.77
1883	4,000	20,000	5.00	1894	7,500	47,500	6.33
1884	4,000	20,000	5.00	1895	4,000	24,000	6.00
1885	5,000	22,500	4.50	1896	6,500	52,000	8.00
1886	5,000	22,000	4.40	1897	5,062	37,159	7.34
1887	5,000	20,000	4.00	1898	7,675	63,050	8.21
1888	6,000	30,000	5.00	1899	15,900	96,650	6.08
1889	9,500	45,835	4.83	1900	18,450	94,500	5.12
1890	8,250	55,328	6.71	1901	19,586	113,803	5.81
1891	10,044	78,330	7.80	1902	48,018	271,832	5.66
1892	12,250	89,000	7.27				

From 1882 up to 1887, the annual production of fluorspar was only 4,000 or 5,000 tons. In the next few years the production increased considerably, reaching 12,400 tons in 1893. Then it fell off to 7,500 tons in 1894 and to 4,000 tons in 1895, thus reaching the figure at which it stood in the years 1882 to 1884. The year 1896 marked the beginning of a second period of increasing production, which appears to be still in progress. In 1899 the production was 15,900 tons, which was more than double that of the preceding year. But the most remarkable increase was in the year 1902, when the quantity produced showed a gain of 28,432 tons, or 145.2 per cent over that of the preceding year, and the value of the product, a gain of $158,029, or 138.9 per cent.

The average value of fluorspar per ton has varied from $4 to $8. The average was exceptionally high in the years 1896 to 1898, inclusive, reaching $8.21 in 1898. In 1902 it was $5.66; the prices reported for that year varied from $2.86 to $11.50 per ton, this higher value being obtained for the fluorspar mined in Arizona, which was used in California. This increase is due to fluorspar being much more largely used than formerly in the fluxing of iron in steel works, and as it is introduced into the smelting of copper and the reduction of other metals, there should be a still further increase in its production.

The imports of fluorspar are not separately stated in the records of the Bureau of Statistics of the Department of Commerce and Labor, but are included with minerals and oils not elsewhere specified.

The detailed statistics of the fluorspar industry for 1902 are shown in Table 4.

DESCRIPTIVE.

Occurrence and use.—Fluorspar is the common name of fluoride of calcium, a mineral occurring in crystals and masses of various colors, very commonly as the gangue of many metallic ores, especially of lead. It is found chiefly in veins in limestone, sandstone, mica slate, clay slate, and gneiss. When it occurs in commercial quantity, it is usually in cleavable masses, and of white, greenish white, or pale green color; but when small openings exist in the veins, the fluorspar is apt to be found in well-developed cubical crystals, which are generally highly colored with various tints of purple, indicating that it is associated with metallic minerals.

Until 1898 the only sources of fluorspar in the United States were the mines in Hardin and Pope counties, in southern Illinois, but during that year deposits were opened in Livingston and Crittenden counties, Ky., and in 1900 in Smith, Trousdale, and Wilson counties, Tenn., and in Yuma county, Ariz. As has been shown above, all these states were producers of fluorspar in commercial quantity in 1902. The mineral has been found widely distributed throughout the United States, but thus far it is only in the four states mentioned that it has been found in sufficient quantity for commercial purposes.

In the fluorspar deposits of Illinois and Kentucky there is known to be a very large supply of this mineral, capable of meeting the demand for many years.

As this overcomes one of the objections often advanced against using fluorspar in the smelting of iron, namely, that a constant supply of this mineral could not be depended upon, its use for this purpose should now increase rapidly. Other hindrances to the use of fluorspar for fluxing purposes have been the higher cost of this flux as compared with limestone, inaccessibility of the deposits, and the action of the slag and gases on the lining of the furnaces. But the recently discovered deposits of Kentucky and Tennessee, together with the deposits in Illinois, furnish an abundant supply, favorably located for transportation, either by railroad or water. The use of chromite (chromic iron ore), either in mineral form or as chrome bricks, will make a lining for furnaces which can be affected but little by the use of fluorspar as a flux. Fluorspar possesses qualities that make it especially adapted for the fluxing of iron, and these should more than compensate for its higher cost, as compared with limestone. Thus far the larger proportion of the fluorspar mined has been used in steel works. Very little is used in blast furnaces or in the smelting of copper or other metals; for these purposes, and also in foundry work, its use will undoubtedly increase rapidly when its value as a flux is more thoroughly understood.

Another use of fluorspar, and formerly its chief use, is in the preparation of hydrofluoric acid. At the present time it is estimated that only from 5 to 10 per cent of the product is used for this purpose. The mineral is also used in the manufacture of opalescent glass, being considered very essential for this purpose.

TABLE 4.—DETAILED SUMMARY: 1902.

	United States.	Illinois.	Kentucky.	All other states and territories.[1]
Number of mines	22	5	14	3
Number of operators	18	5	10	3
Character of ownership:				
Individual	2	1	.....	1
Firm	2	1	1	.....
Incorporated company	14	3	9	2
Salaried officials, clerks, etc.:				
Total number	42	9	31	2
Total salaries	$27,311	$5,304	$21,107	$900
General officers—

[1] Includes operators distributed as follows: Arizona, 2; Tennessee, 1.

GYPSUM

GYPSUM.

By Story B. Ladd.

The statistics presented herewith comprise those for gypsum in its calcined form as well as in its natural state. The chief consumption of gypsum is for the manufacture of plaster of Paris and wall or cement plaster, of which plaster of Paris is the chief ingredient. At the Tenth Census no statistics in regard to gypsum were reported, and at the three decades prior thereto, namely, 1870, 1860, and 1850, only the manufacturing statistics for plaster are available for purposes of comparison. Table 1 is a comparative summary for the years 1850, 1860, 1870, 1889, and 1902.

Table 1.—*Comparative summary: 1850 to 1902.*

	1902	1889	1870	1860	1850
Number of mines or quarries	62	[1]	[1]	[1]	[1]
Number of operators	45	[1]	[2]321	[2]307	[2]140

Number	249	[3]	[3]	[3]	[3]
Salaries	$300,420	[3]	[3]	[3]	[3]
Wage-earners:					
Average number	1,472	761	1,513	866	381
Wages	$759,258	$249,200	$533,407	$232,500	$100,692
Contract work	$406	$10,031	[1]	[1]	[1]
Miscellaneous expenses	$200,769	$45,262	[1]	[1]	[1]
Cost of supplies and materials	$341,760	$128,854	$1,430,140	$522,836	$239,063
Product[4]:					
Quantity, short tons	681,633	246,725	[1]	[1]	[1]
Value	$2,089,341	$764,118	$2,691,851	$1,110,854	$428,914

[1] Not reported.
[2] Establishments.
[3] Not reported separately.
[4] The United States Geological Survey reports 816,478 short tons of crude gypsum, of the value as here given. The Census figures of quantity are for the product prepared, in greatest part, for the market.

In 1850 the value of the land-plaster product was given as $428,914. In 1860 the value of plaster and its manufactures was $1,110,854, and presumably the largest portion of this amount was land plaster. In 1870 the amount of plaster manufactured, reported as "Plaster, ground," and presumably chiefly used for land plaster, reached $2,691,851. Up to this time there appears to have been a steady growth in the use of gypsum as a fertilizer, but with the development of the phosphate rock industry, which began just prior to the close of the decade ending in 1870, came a corresponding reduction in the use of gypsum for land plaster, and in 1880 the total gypsum production, as reported by the United States Geological Survey, was but 90,000 short tons, valued at $400,000.

The mining of phosphate rock commenced in South Carolina in 1867, and in 1870 the production was 65,241 long tons. In 1880 the sales of phosphate rock in the United States amounted to 211,377 long tons, valued at $1,123,823, while the gypsum product had fallen, as above noted, to a value of $400,000. In 1889 the sales of phosphate rock were 550,245 long tons, valued at $2,937,776. Florida had lately become a producer. On the other hand, the ground gypsum sold as land plaster in 1889 was but 108,771 short tons, valued at $233,307, in contrast with the production for 1870 of ground plaster, valued at $2,691,851.

The shrinkage in the consumption of gypsum for land plaster continues, the growth in the gypsum industry since 1889 being due to the increasing use of wall or cement plaster. In 1889, 108,771 tons, or 40.6 per cent, of the gypsum was sold as land plaster; in 1902 only 60,791 tons, or 7.4 per cent.

The growth of the industry during the period 1889 to 1902 has been entirely in the production of calcined gypsum. In 1889, 85,755 tons of gypsum, or 32 per cent of the amount quarried, were calcined, while in 1902 the quantity calcined was 674,232 tons, or 82.6 per cent of the gypsum quarried, producing 539,387 tons of calcined plaster products—plaster of Paris and wall or cement plaster. Along with the increased consumption of calcined plaster there was a decrease in the average price from $6.92 per ton in 1889 to $3.50 per ton in 1902. There was no material change in the average price of crude gypsum, it being $1.13 per ton in 1889 and $1.15 per ton in 1902. The average value of the land plaster, however, decreased from $2.14 per ton in 1889 to $1.75 per ton in 1902.

A change in the character of the industry is also shown by the reduction in the number of operators. In 1870, 321 operators were reported, and in 1902 only 45. The number of mines, which in 1870 must have been at least 321—that being the number of operators—was only 62 in 1902. The production of land plaster requires small capital, the gypsum being simply mined or quarried and ground; and the average values of the product per operator for the years 1850, 1860, and 1870—$3,064, $3,910, and $8,386, respectively—indicates that during that earlier period, when land

plaster was the principal or sole product, this industry was small and local in character. The statistics for 1902 show a concentration of the business. The 62 producing mines or quarries were controlled by 45 operators and the average value of the product per operator was $46,430. Of the 62 active mines or quarries, 19 were operated by 2 companies. The reduction in the number of operators and active mines or quarries reflects the growth of the wall plaster industry, which has a wider market and requires a much larger capital and plant than the mere manufacture of land plaster.

During the period from 1889 to 1902, the value of the product increased 173.4 per cent, the wage-earners 93.4 per cent, and the amount paid in wages 204.7 per cent.

There were 17 idle mines or quarries in 1902, distributed as follows: 8 in New York, 3 in Arizona, and 1 each in Kansas, Missouri, New Mexico, Ohio, Texas, and Virginia. These were owned by 9 individuals, 1 firm, and 5 incorporated companies. Two of the mines in Arizona were owned by 1 individual. Two of the other idle mines, 1 in Kansas and 1 in Missouri, were owned by 1 corporation, which operated 16 active mines or quarries in Iowa, Kansas, Michigan, New York, Ohio, and Oklahoma. The statistics of the capitalization of this corporation are included among those of the active mines. The remaining 4 incorporated companies were located 1 each in New York, New Mexico, Ohio, and Texas. Three of these did not report capitalization. The fourth company reported an authorized capital stock of 250,000 shares, with a par value of $250,000; all of the common stock, 200,000 shares of a par value of $200,000, had been issued. It reported also authorized bonds of a par value of $25,000, of which $15,000 had been issued, making a total of $215,000 for stocks and bonds issued.

Of the 45 operators in 1902, 13 were individuals, 6 were firms, and 26 were incorporated companies. Only 3.6 per cent of the gypsum mined or quarried was produced by the 19 individuals and firms, and in Iowa, Kansas, Michigan, Oklahoma, Texas, and Utah the operators were solely incorporated companies.

Capital stock of incorporated companies.—Table 2 presents the details of the capitalization of the incorporated companies.

TABLE 2.—CAPITALIZATION OF INCORPORATED COMPANIES: 1902.

	United States.	Kansas.	Michigan.	New York.	Oklahoma.	All other states.

[1] One of these companies operated mines and quarries in Iowa, Kansas, New York, Ohio, and Oklahoma, as well as in Michigan.
[2] Includes companies distributed as follows: Iowa, 3; Texas, 2 (1 company operating quarries also in Oklahoma and Wyoming); Utah, 1; Virginia, 1; Wyoming, 1.

Of the 26 incorporated companies, 6 were in New York, 5 in Kansas, 4 in Michigan, 3 each in Iowa and Oklahoma, 2 in Texas, and 1 each in Utah, Virginia, and Wyoming. These companies operated 43 mines or quarries distributed as follows: 9 in Iowa, 8 in New York, 7 in Kansas, 6 in Michigan, 5 in Oklahoma, 2 each in Ohio, Texas, and Wyoming, and 1 each in Utah and Virginia. The capitalization was reported for all of the incorporated companies, with the exception of 1 company in Iowa not engaged exclusively in the mining or quarrying of gypsum and the manufacture of its products. The authorized capital stock consisted of 61,580 shares of common stock of a par value of $6,046,665, and 45,300 shares of preferred stock of a par value of $4,530,000; at the close of the year covered by this investigation, 60,998 shares of common stock of a par value of $5,995,965, and all of the preferred stock had been issued. The authorized bonded indebtedness comprised 1,645 bonds of a par value of $1,145,000, of which there had been issued 145 bonds of a par value

of $145,000. The outstanding capital stock and bonds issued aggregated $10,670,965.

The interest paid on the bonded debt was $2,700; the small amount is explained by the fact that the organization of several of the companies occurred during 1902, and only 2 companies reported the payment of interest on bonds aggregating $45,000. Dividends amounting to $64,300 were paid by 6 companies, distributed 1 each in Iowa, Kansas, Michigan, Oklahoma, Texas, and Utah. The capitalization of 1 company operating mines or quarries in Iowa, Kansas, Michigan, New York, Ohio, and Oklahoma was credited to Michigan, as its largest production was from that state; and, in like manner, the capitalization of 1 company operating mines or quarries in Oklahoma, Texas, and Wyoming was credited to Texas, where its largest plant was located.

Employees and wages.—Of the total amount, $1,059,678, reported as paid for salaries and wages, $759,258, or 71.6 per cent, was paid to the wage-earners, and $300,420, or 28.4 per cent, to the salaried employees.

The variation in the number of wage-earners employed at different seasons of the year is shown in Table 6, which gives the average number of men and boys employed during each month. The employment of boys under 16 is reported only in the case of 1 mine. The least average number of wage-earners employed during any month was 773 in January, and the largest average number for any month was 1,696 in September. For the remaining months the number fluctuated within a comparatively narrow range. The number of wage-earners employed at specified daily rates of pay is also shown in Table 6.

The prevailing rate of pay for wage-earners was from $1.50 to $1.74 per day, 754, or 51.2 per cent, receiving this rate. The per cent receiving less than $1.25 per day was only 2.5; 5.6 per cent received from $1.25 to $1.49; 23 per cent, from $1.75 to $1.99; 10.2 per cent, from $2 to $2.24; 3.3 per cent, from $2.25 to $2.49; 2.5 per cent, from $2.50 to $2.74; and 1.7 per cent received $3 and over. Of the total number of wage-earners 614, or 41.7 per cent, were classed as miners or quarrymen. Of these 329, or 22.4 per cent, received from $1.50 to $1.74 per day. Nine received from $3 to $3.24 per day.

Mining and quarrying on a tonnage basis was reported by 18 mines or quarries, at rates ranging from a minimum of $0.20 per ton to a maximum of $0.65 per ton, with an average of $0.445 per ton. These mines or quarries were distributed as follows: 7 in Iowa, 4 in New York, 2 in Kansas, and 1 each in California, Michigan, Oklahoma, Texas, and Utah.

Supplies, materials, and miscellaneous expenses.—The total amount reported for supplies and materials was $341,760. In the case of operators producing uncalcined gypsum only, either crude gypsum or land plaster, the expense for supplies and materials was small, only 5 or 10 cents per ton.

The total amount reported for miscellaneous expenses was $200,769, of which amount $49,912 was paid by 20 mines or quarries for royalties and rent of mine and mining plant; and $150,857 for rent of offices, taxes, insurance, interest, and other sundries. The mines or quarries reporting the payment of royalties and rent of mine and mining plant were distributed as follows: Six in New York, 4 in Kansas, 2 each in Iowa, Ohio, Oklahoma, and Wyoming, and 1 each in Texas and Virginia.

Mechanical power.—Of the 62 mines or quarries operated, 55 reported power, the primary power employed aggregating 7,319 horsepower. Where mills were operated in conjunction with the mine or quarry, this includes mill power as well as power directly employed in mining or quarrying. The power was supplied by 68 steam engines, aggregating 6,385 horsepower; 2 gas or gasoline engines with a total of 20 horsepower; and 11 water wheels having 914 horsepower. There were, in addition, 5 electric motors with a capacity of 68 horsepower.

Production.—The total production for the year 1902 was 816,478 short tons of gypsum quarried, of which 674,232 tons were calcined, producing 539,387 tons of calcined plaster—plaster of Paris and wall or cement plaster—valued at $1,889,190. There were sold in the crude state 81,455 tons of gypsum, valued at $93,914, an average price of $1.15 per ton; and 60,791 tons ground for land plaster, valued at $106,237, an average price of $1.75 per ton. The 539,387 tons of calcined products comprised 188,702 tons of plaster of Paris, valued at $562,928, an average price of $2.98 per ton; and 350,685 tons of wall or cement plaster, valued at $1,326,262, an average price of $3.78 per ton. The production of the 188,702 tons sold as plaster of Paris consumed 235,878 tons of crude gypsum; and the production of the 350,685 tons of wall or cement plaster consumed 438,354 tons of gypsum before calcination into plaster of Paris and manufacture into wall or cement plaster. The increase in the marketable gypsum products for 1902 over those of 1889 was in quantity 434,908 tons, or 63.7 per cent, and in value $1,325,223, or 173.4 per cent.

Of the calcined products 65.3 per cent was wall or cement plaster, including all of the calcined product from the states of Nevada, South Dakota, and Utah; 90 per cent and over of that from California, Kansas, Montana, Oklahoma, Texas, and Wyoming; from 80 to 90 per cent of that from Iowa and Oregon; 60 per cent of that from Colorado, and less than 50 per cent only from Michigan, New York, Ohio, and Virginia.

Table 3 shows the production of gypsum in the United States from 1880 to 1902, as reported by the United States Geological Survey.

[1] Marketable products, 246,725 short tons.
[2] Marketable products, 681,633 short tons.

Beginning with the year 1899 there was shown a marked annual increase in the quantity of gypsum produced. The increase in 1899 was 66.7 per cent; in 1900, 22.3 per cent; in 1901, 12 per cent; and 1902, 24 per cent. The total increase from 1898 to 1902 was 524,840 tons, or 180 per cent.

The imports of gypsum from 1889 to 1902 are shown in the following table:

The detailed statistics for the gypsum industry during 1902 are given in Table 6.

DESCRIPTIVE.

Gypsum, a natural product, is calcium sulphate, of the chemical formula $CaSO_4.2\,H_2O$, containing 46.5 per cent of sulphuric acid, 32.6 per cent of lime, and 20.9 per cent of water. Anhydrite, a mineral like gypsum, but, as its name indicates, containing no water, is composed of 58.8 per cent of sulphuric acid and 41.2 per cent of lime. This absorbs water and changes to gypsum. When gypsum is properly calcined it loses a part of the water of its composition and becomes plaster of Paris, the name originating from the great deposits of gypsum worked at Montmartre, a suburb of Paris. The transparent crystallized variety of gypsum is called selenite; its fine massive variety, alabaster; and its fibrous form, satin spar. A loose earthy gypsum found in Kansas and other points in the West is called gypsite.

Gypsum crystallizes in the monoclinic system, has a hardness of 2, and a specific gravity of 2.31. Its color is usually white, although sometimes red, green, blue, gray, or brown. When protected from the action of water it is extremely durable, as evidenced by the numerous monumental effigies, many centuries old, in European churches and elsewhere.

It is quite generally distributed and occurs in irregular and often in very extensive and massive deposits. A deposit of white crystalline gypsum at Netherfield, England, is more than 50 feet in thickness, and in the Thüringerwald, Germany, a great mass has been sunk through to a depth of 70 feet. The gypsum deposits of Onondaga county, N. Y., show in places a thickness of 60 feet. The snow-white alabaster found at Volterra,

in Tuscany, Italy, is used extensively at Florence and Leghorn for works of art. It is white when newly broken and on drying becomes even whiter on the surface. It is easily cut and turned and under proper treatment takes a fine polish and satin luster.

Origin.—Gypsum deposits have been formed by direct deposition, and by the alteration of existing lime deposits. Most of the gypsum deposits of the world are considered to have been formed by the evaporation and concentration of sea water, although the calcium sulphate is not deposited until about 80 per cent of the water has been evaporated. Sea water, according to the analyses in the Challenger Reports, contains 3.5 per cent of mineral matter of the following constituents:

	Per cent.
Sodium chloride (salt)	77.758
Magnesium chloride	10.878
Magnesium sulphate	4.737
Calcium sulphate (gypsum)	3.600
Potassium sulphate	2.465
Calcium carbonate	0.345
Magnesium bromide	0.217
	100.000

When such a body of water cut off from the ocean is evaporated, the calcium sulphate is deposited before the sodium chloride, the latter being thrown down only after the removal of 93 per cent of the water. With complete evaporation and deposition there would be, therefore, first a deposit of gypsum and then a heavy deposit of salt, though the evaporation may go far enough to deposit the gypsum, but not far enough to deposit the salt; or if the latter be deposited it may be removed subsequently by solution. Gypsum deposits, therefore, are more widely spread than salt, but usually occur in thinner beds.

When sulphuric acid, liberated by the decomposition of pyrite, acts on calcium carbonate and converts it into calcium sulphate, there is generally a gradual transition from the limestone into the gypsum rock.

Gypsum is deposited by some thermal springs, as in Iceland, where the sulphurous acids on becoming oxidized change to sulphuric acid, which converts the calcium carbonate into calcium sulphate, and this when evaporation takes place is deposited in fibrous and crystalline forms.

The theory of Dawson on the origin of gypsum at Plaister Cove, Nova Scotia, is as follows: First, there was an accumulation of numerous thin layers of limestone, either so rapidly or at such great depths that organic remains were not included in any but the upper layers. Second, there was an introduction of sulphuric acid, in solution or in vapor, which was a product of volcanic action. Then for a long time the acid waters acted upon the calcareous material without interruption from mechanical detritus, changing the calcium carbonate to calcium sulphate, and gypsum of good quality accumulated in considerable thickness.

Occurrence.—Gypsum is widely distributed geologically, being found in various formations ranging from the Silurian up to the Tertiary. In New York extensive beds of gypsum are found in the Silurian formation; in Ohio and Michigan they occur in the Carboniferous; and in Iowa and Kansas they are Cretaceous.

Gypsum is also widely distributed geographically. In the United States it is found in Arizona, California, Colorado, Iowa, Kansas, Michigan, Montana, Nevada, New Mexico, New York, Ohio, Oklahoma, Oregon, South Dakota, Texas, Utah, Virginia, and Wyoming, and is mined in all these states except Arizona, Missouri, and New Mexico. It is found in Arabia, Austria, Bohemia, Canada, Egypt, England, France, Germany, Italy, Norway, and Persia.

Use.—The use of gypsum was known at a very early period, for the Greeks were familiar with it, as shown by the writings of Theophrastus and Pliny. Gypsum in its ground, uncalcined state is used chiefly for land plaster, a fertilizer. In its calcined form, as plaster of Paris, it has extensive and varied uses.

Land plaster.—Ground plaster has long been used as a fertilizer. Virgil wrote concerning the value of gypsum on cultivated lands. Benjamin Franklin called attention to the value of gypsum as a fertilizer for grass by sowing land plaster in a clover field, so as to form the sentence, "This has been plastered with gypsum," the letters showing by the height and color of the clover where gypsum had been sown.

Numerous experiments and tests are on record as to the value of gypsum as a fertilizer. Boussingault in 1841 fertilized a clover field with gypsum and analyzed the clover grown on fertilized and on untertilized land. These experiments were conducted for two years on the same land, and the analyses of the ash of the clover from a hectare of ground showed as follows, in kilograms:

Analyses of clover.[1]

	1841		1842	
	Land with gypsum.	Land without gypsum.	Land with gypsum.	Land without gypsum.
Ashes free from CO_2	270.0	113.0	280.0	97.0
Silica	28.1	22.7	10.4	12.7
Oxide (iron, manganese, alumina)	2.7	1.4	(?)	0.6
Lime	79.4	32.2	102.8	32.2
Magnesia	18.1	8.6	28.5	7.1

Soda	2.4	1.4	0.8	2.8
Sulphuric acid	9.2	4.4	9.0	3.0
Phosphoric acid	24.2	11.0	22.9	7.0
Chlorine	10.3	4.6	8.4	3.0

[1] The University Geological Survey of Kansas, Vol. V, Report on Gypsum and Gypsum Cement Plasters.

This shows an increase in all the mineral constituents, but especially in lime, magnesia, and potash.

The theories of the action of gypsum as a fertilizer have been many. Sir Humphry Davy and others before and after his time have regarded gypsum as a direct source of plant food. It is now thought that gypsum acts as a fertilizer in three ways, one mechanical and two chemical:

(1) The gypsum by mechanical action flocculates loose soils.

(2) Gypsum as pointed out by Storer[1] has nearly one-half its weight in oxygen and gives this up to many substances, and so may act upon nitrogenous and carboniferous substances in the soil.

(3) Gypsum decomposes the double silicates in the earth, setting free potash as a soluble silicate. According to Storer, the action is as follows:

$$\left.\begin{matrix}Al_2O_3\\CaO\\K_2O\\H_2O\end{matrix}\right\}XSiO_2 + CaOSO_3 = \left\{\begin{matrix}Al_2O_3\\CaO\\CaO\\H_2O\end{matrix}\right\}XSiO_2 + K_2OSO_3$$

By this means the potash in solution reaches the roots of the plants. Soils with abundant potash do not need land plaster, and soils with no potash compounds are not benefited in this respect by it.

Plaster of Paris.—The phenomena attendant upon the baking and hardening of plaster of Paris were first studied by Lavoisier. In the Comptes Rendus of February 17, 1765, appears the following: "After having removed the water of hydration from gypsum by heat, if it be presented to it again (this is commonly known as the mixing or tempering of plaster), it takes it back with avidity, and suddenly assumes a state of irregular crystallization; the small crystals which form become confused with each other, the result being a very hard mass." Lavoisier discovered that when plaster was baked at too high a temperature it lost its peculiar property of setting, and that when it was heated the water of crystallization was removed at two different stages, three-fourths of it being much more easily removed than the remainder. Payen, in 1830, found that gypsum began to lose its water of crystallization at 115° C., and that the loss increased rapidly as the temperature rose. He concluded that a temperature of from 110° to 120° C. was the best for calcination, but that plaster of Paris could be made at a lower temperature, even as low as 80° C., if the burning were continued long enough. He found that gypsum was dehydrated if heated to about 250° C., and from 300° to 400° C. it lost completely the properties of hydration.

Le Chatelier experimented in 1887 on the effects of temperature on gypsum. On heating gypsum to 200° C., he found that there was a constant rise in temperature, with two breaks; the first halt at 128° C. and the second at 163° C., indicating the existence of two different hydrates, whose decomposition took place at the temperatures stated. The dehydration was found to be incomplete at 155° C. and complete at 194° C.

An analysis of the first hydrate gave:

	Per cent.
Water	6.7
Calcium sulphate	93.3
	100.0

This agrees very closely with the formula $(CaSO_4)_2 H_2O$, which gives:

	Per cent.
Water	6.2
Calcium sulphate	93.8
	100.0

Gypsum has 1 part of calcium sulphate united with 2 parts of water, while this hydrate shows 2 parts of calcium sulphate united with 1 part of water. The same hydrate is found in the incrustation of the boilers of ocean steamers when fed with sea water, as shown by the following analysis:

Analysis of boiler incrustation from a trans-Atlantic steamer.

	Per cent.
Calcium carbonate	0.3
Ferric oxide	2.0
Water	5.8
Calcium sulphate	91.9
	100.0

The temperature at which this compound is completely dehydrated lies between 160° and 170° C. Broken up and mixed with water, it hydrates and hardens. Further experiments showed plaster of Paris to be a definite hydrate with the formula $(CaSO_4)_2H_2O$.

The second halt noticed in Le Chatelier's experiments took place at 163° C., and from this temperature to 221° C. no change was noted in the plaster, but beyond 221° C. the plaster, when mixed with water, did not absorb it readily and set only after a long time. If the heat reaches 343° C., the plaster acts like an anhydrite and is said to be "dead burned." It will not set on the addition of water. When heated still more the substance melts and, on cooling, forms a crystalline mass, which can not be decomposed by heat, except in the presence of organic matter, when it changes into CaS. If this substance is acted upon by carbon dioxide gas (CO_2) and water, sulphureted hydrogen gas is formed.

The burning of gypsum is, therefore, a very important matter, and calciners become very expert. If the gypsum is underburned, the new hydrate is not formed, and the plaster will not set. If it is overburned, the plaster sets very slowly.

Lavoisier gave the following account of his theory of set in plaster:

I took the calcined plaster, which hardens readily with water, and threw it into a considerable amount of water. Each molecule of plaster, in passing through the liquid, seized its molecule of water of crystallization and fell to the bottom in the form of small brilliant needles, visible only with a strong lens. These needles, dried in the open air or with the aid of a moderate heat, are very

[1] Chemistry of Agriculture, Vol. I, 1887, pages 206 to 216.

soft and silky to the touch. Under a microscope it is perceived that what was taken under the lens for needles are also parallelopipeds, very fine, some thicker, many thinner, and many more elongated. The plaster in this state is not capable of uniting with water, but if it is calcined anew these small crystals lose their transparency and their water of crystallization and become again a true plaster, as perfect as before. One may, in this fashion, successfully calcine and recrystallize the plaster, even to infinity, and consequently give to it at will the property of seizing water.

Landrin, who, in a paper published in 1874,[1] quoted the above, and gave the results of a study of plaster, divided the set of plaster into four periods as follows:

(1) The calcined plaster, on contact with water, unites with this liquid and takes a crystalline form.

(2) The plaster dissolves partially in the water, which becomes saturated with this salt.

(3) A part of this liquid evaporates, due to the heat set free in the chemical combination. A crystal is formed and determines the crystallization of the entire mass, a phenomenon which is analogous to that which takes place when a piece of sodium sulphate is placed in a saturated solution of this salt.

(4) The maximum hardness is reached when the plaster loses enough water to correspond exactly to the formula $(CaSO_4)_2H_2O$, this maximum being to the remainder in proportion to the quantity of water added to the plaster to transform it into mortar.

The maximum hardness then was reached when the plaster contained about 20 per cent of water. Landrin believed that the loss of water was due to the evaporation.

Le Chatelier showed that plaster would set in a vacuum, so that evaporation was not a necessary step. According to Le Chatelier, the plaster of Paris dissolves, becomes hydrated, and then crystallizes out as gypsum, and every particle of the plaster goes through these steps.

Microscopic examination[2] shows that ground gypsum, before calcination, is composed of rather large masses of various sizes, these masses consisting of more or less broken crystals. After calcination these larger masses are broken up into fine granules nearly uniform in size and shape. As the material is heated, the water is changed into steam and, expanding, breaks the crystals into finer particles. There is thus a physical change, as well as a chemical one.

When water is added to the calcined plaster, small needle-like crystals are seen forming and shooting out here and there, and these, as they become more abundant, unite and form a solid mass, in which the individual crystals can scarcely be distinguished. Open spaces left in the mass are finally closed and a firm solid mass results.

Uncalcined gypsum treated with water shows, under the microscope, very little change. Gypsum crystallized by evaporation shows crystals which are not needle-shaped, but broader and of considerable irregularity. They do not interpenetrate, but form a loose mass which readily crumbles.

Crystallization is aided by the small size of the grains, and the finer-grained plasters set more rapidly than the coarser-grained ones, as shown by the comparison of the fine dental plasters with ordinary plaster of Paris.

Manufacture.—In the manufacture of plaster of Paris the gypsum rock is crushed and ground into flour in a buhr mill, a roller mill, or a disintegrator. The ground gypsum is then passed into storage bins. In some mills the flour gypsum is conveyed to the bins by an air blast.

The calcining kettles are made of boiler steel and hold about 8 tons; the flame is carried around the sides, by flues, so as to heat all parts. In charging, the ground gypsum is run slowly into the kettle, which is kept at a temperature of 212° F. or over; about an hour and a half is consumed in filling to a depth of 5 feet. The material is kept in motion by a mechanical stirrer, it being of the greatest importance that the partly calcined plaster shall not remain in contact with the heated iron. The slow filling tends to keep the heat constant or nearly so during the charging, and as the boiling increases the plaster is occasionally thrown in "waves" out of the kettle. The heated material boils like thick cream, and runs almost like water. The boiling is, of course, due to the escape of the water of crystallization and the hygroscopic water that may be present. The boiling takes about three hours; a short time before completion, when the temperature reaches 270° F., there is a sudden settling down and the steam ceases to rise, marking the period of formation of the first hydrate. Soon the mass begins to boil again; after a certain time, quite accurately determined by the expert calciner, when a temperature of approximately 350° F. is reached, the charge is done, the discharge gate is opened, and the finished product runs out into a vault. The refilling of the kettle for the succeeding charge begins at once.

Retarders.—As plaster of Paris, when mixed with water, sets in from six to ten minutes, material is incorporated therewith, either during its manufacture or at the time of its preparation for use, to delay or hold back the set, in order that the cement plaster can be prepared in quantity and applied with uniform results. These compounds or admixtures are known as retarders or restrainers. In the early days of cement plaster, glue was added by the workman when he prepared the material for use; but now, to secure uniform results, the retarder is, as a rule, incorporated with the plaster in the process of manufacture. Citric acid was used for a time, but this was expensive, and the results were often uneven. As magnesian limes set more slowly than calcareous limes, it was thought that the addition of magnesian limestone would serve as a retarder, but the use of this substance is said not to be a success.

[1] Annales de Chimie, 1874.

[2] University Geological Survey of Kansas, Vol. V, Report on Gypsum and Gypsum Cement Plasters, pages 92 to 95.

In the days of the Romans, blood was used to retard the set of plaster of Paris, and organic matter from slaughterhouse refuse (tankage, bones, hair, etc.), forms the base of many of the retarders now in use.

Any substance which, when added to the water with which calcined gypsum is mixed, or to the dry plaster, will keep the molecules apart or from too close contact will delay the crystallization and retard the setting. Such substances are dirt or organic matter not of a crystalline character. Insoluble material or carbonates of the alkaline earths will dilute the plaster so that it will not set as quickly as the unadulterated plaster. Whether a retarder weakens the cement plaster or not is a disputed question among architects and plasterers, although it is conceded that the addition of too much foreign material reduces the strength of the mass of interlacing crystals. As a general rule the prolongation of the period of crystallization or set is determined by the quantity of retarder added to or incorporated with the plaster. Calcined plaster which sets slowly, whether retarded or not, is known as cement plaster.

Accelerators.—It is a well-known fact that when a salt crystal is dropped into a supersaturated solution of a salt, as for instance sodium sulphate, the whole mass immediately crystallizes. Crystals, or even solid particles of foreign material, will hasten the crystallization. Hence, to make a quick-setting plaster, as for dental use, some other crystallizing salt, as alum or borax, is added, in small quantity, to the calcined gypsum. The result is that, after solution, the added salt has a tendency to crystallize, and thus starts the process in the dehydrated gypsum.

Processes for hardening plaster.—When calcined gypsum is steeped in a solution containing from 8 to 10 per cent of alum, and then dried and again burned with a dull red heat of uniform and constant temperature (Greenwood's process), a plaster is produced which after setting is very much harder than the ordinary plaster. Casts made of such plaster solidify gradually, but finally acquire a hardness similar to that of alabaster or marble, and present a translucent appearance resembling these substances. According to Landrin, this change in the plaster is not to be accounted for by the formation of double sulphates of lime and alkali, nor by the crystals of calcium sulphate being embedded in alumina; but rather by the calcium carbonate in the plaster stone being converted by the alum into calcium sulphate. A liquid containing from 8 to 10 per cent of sulphuric acid acts in a similar manner. Landrin analyzed alum plasters with the following results:

Landrin's analyses of alum plasters.

DESCRIPTION OF SPECIMENS (ALUM PLASTERS).	$CaSO_4$.	CONSTITUENTS.			
		$CaCO_3$.	SiO_2.	H_2O.	Total.
French cement	96.75	1.05	0.72	1.48	100
English cement, No. 1	98.19	0.41	.....	1.40	100
English cement, No. 2	98.02	0.37	0.42	1.19	100
Stucco	98.05	0.36	0.51	1.08	100

These figures show that the alum cements are of great purity and have no trace of alumina or potash.

Keene's hard cement is produced by impregnating plaster of Paris with a solution of 1 part of borax and 1 part of cream of tartar in 18 parts of water, drying and burning at a low red heat for six hours. Borax alone serves the purpose. The plaster hardens more slowly as the solution is more concentrated.

Silicated plaster is formed by sponging the surface of plaster casts with a solution formed by first adding whey, free from fatty matter, to a potash lye solution made by adding 1 part of potash to 5 parts of water, and afterwards mixing 4 parts of this with a simple solution of potassium silicate.

Stearin melted at not too high a temperature has been employed as a bath in which plaster casts are immersed.

Landrin found that lime had great influence on plasters. By mixing lime with the plaster in different proportions, not to exceed 10 per cent, he obtained plaster which set regularly, became very hard, and took a high polish.

A large number of patents have been issued for retarding compounds and admixtures, and for prepared plasters, as well as for processes of manufacture and for hardening gypsum, and a digest of the same will be found in an appendix. There have also been issued some 280 or more patents for improvements in the arts involving the use of gypsum or plaster of Paris in the manufacture of artificial stone, wall and roofing cements, pavements, crayons, blackboards, heat insulating composition, etc.

TABLE 6.—DETAILED SUMMARY: 1902.

	United States.	Iowa.	Kansas.	Michigan.	New York.	Oklahoma.	Wyoming.	All other states.[1]

APPENDIX.

DIGEST OF UNITED STATES PATENTS.[1]

GYPSUM AND PLASTER OF PARIS.

I—PROCESSES.

II—RETARDERS.

I—*Processes.*

1361—October 9, 1839. J. D. GREENWOOD and R. W. KEENE. *Cement for forming artificial stone.*

Gypsum is saturated with water in which 1 pound of alum to the gallon has been dissolved and then dried and calcined.

211066—December 17, 1878. C. T. TOMKINS. *Preparing gypsum for use in paper making and other purposes.*

Minutely crystalline sulphate of lime is formed by subjecting gypsum to continuous agitation in a tank with water and to a continuous circulation.

308111—November 18, 1884. J. H. TRICKEY. *Art or process of and composition for making artificial stone.*

It is composed of plaster of Paris, glycerin, and water, and is boiled in a solution of brimstone after becoming set and dried.

309612—December 23, 1884. R. B. EASON and J. J. MCGEVENY. *Cement composition for molding brick, etc.*

A mixture of gypsum and ashes in about equal proportions in a dry pulverized state is boiled in water without agitation until the water is evaporated and the mass dried out.

326047—September 8, 1885. W. MANNING. *Process of treating gypsum.*

Alabaster in the form of a dry precipitated powder is formed by subjecting gypsum to grinding, calcining, and agitation in water, then floating in a floating apparatus, then forcing through a filter, and afterwards drying, crushing, and grinding.

342784—June 1, 1886. U. CUMMINGS. *Manufacture of cement.*

For the manufacture of a hydraulic or Portland cement a mixture of clay 400 pounds and gypsum 1,266 pounds is calcined.

343181—June 8, 1886. E. W. MARSH. *Process of calcining gypsum.*

Ground gypsum in a suitably constructed kettle is exposed to the heat of superheated steam.

395159—December 25, 1888. W. MANNING. *Process of treating gypsum.*

To produce an impalpable opaque anhydrous powder, gypsum is subjected to a second calcination and subsequent reduction by crushing and grinding.

519259—May 1, 1894. H. C. HIGGINSON. *Manufacture of plaster.*

The plaster is heated to about 395°, then cooled to about 365°, and then given a temperature of about 380° and discharged at such temperature.

549151—November 5, 1895. G. W. PARKER. *Process of treating gypsum rock to imitate chalcedony.*

The rock is dehydrated by the action of hot air, and the porous rock is then allowed to absorb a solution of sulphate of iron, nitric acid, and potassium sulphocyanide, after which it is immersed in a solution of aluminum sulphate, $Al_2(SO_4)_3$, for 15 hours, then exposed to the air and polished.

588287—August 17, 1897. G. W. PARKER. *Process of treating gypsum rock to imitate marble.*

The moisture is first removed from the rock by the action of hot air, then the hot rock is placed in a closed compartment charged with the fumes of ammonia, and the cool rock is then immediately immersed in a solution of aluminum sulphate until the pores are filled.

624709—May 9, 1899. F. P. VAN HOOK. *Method of producing plaster products.*

The material is calcined to a pulverulent condition and then, while intensely heated, subjected to the action of a current of cold air of such strength that the particles are taken up and carried in suspension, and rapidly cooled.

655501—August 7, 1900. L. H. MERCERON-VICAT. *Artificial cement.*

Natural marly limestone, or a prepared mixture of calcareous matter and clay, containing sulphur, is calcined and then fused under oxidizing conditions, thereby removing the sulphur while the materials are in a state of fusion.

661247—November 6, 1900. W. R. JOHNSON. *Process of revivifying old plaster of Paris.*

It is subjected to two heatings and an intermediate wetting with acidulated water, the first heating effecting a more complete removal of water than the second, while the intermediate wetting serves to rehydrate the burnt plaster.

674760—May 21, 1901. A. E. CUMMER. *Process of treating hydrous compounds.*

The raw material is heated until dehydration has commenced and has been partially completed, and then the dehydration is completed by the resident heat of the material out of contact with the air.

678412—July 16, 1901. W. LESSING. *Process of burning cement, gypsum, etc.*

The ground raw material is heated to a white heat and dropped downwardly against a column of flame, then cooled, and the resulting heat used for generating steam and for the preliminary warming of the material.

II—*Retarders.*

101253—March 29, 1870. A. H. FREAR. *Manufacture of artificial stone.*

Employs an aqueous saccharine solution of litharge in the manufacture of artificial stone.

165533—July 13, 1875. A. BOAG. *Composition for stone cements.*

Calcined gypsum is saturated with a solution of 1 pound of saltpeter to 4 gallons of water; it is then dried and ground.

225261—March 9, 1880. O. F. WOODWARD. *Composition for making molded articles of manufacture.*

Gypsum and rosin, say in the proportion of 125 pounds of gypsum and 100 pounds of rosin, are mixed together under heat.

[1] Printed copies of patents are sold by the Commissioner of Patents at 5 cents each.

291508—January 8, 1884. H. Graf. *Plastering composition.*

Uses glue and glycerine, together with plaster of Paris, slaked lime, sawdust, and hair.

321620, 321621—July 7, 1885. E. and E. W. Marsh. *Composition of matter to be used as a plaster for building purposes.*

Uses as retarder resin lac dissolved in a solution of caustic soda.

368594—August 23, 1887. G. R. King. *Compound to restrain the setting of plaster.*

The restrainer consists of glue and ground stone.

390157—September 25, 1888. J. Coy. *Composition of matter for plastering, etc.*

The restrainer consists of glue, Irish moss, molasses, and tartaric acid.

391889, 391890—October 30, 1888. J. H. Fitzgerald. *Plastering composition.*

Uses sugar as a restrainer.

392528—November 6, 1888. C. Straub. *Composition of building material for architectural purposes.*

Magnesia is mixed with dissolved glue or gelatinous matter, hydrocarbon compound, acid, and pulverized calcined material, the magnesia producing a smooth and glossy surface.

397296—February 5, 1889. G. R. King. *Compound to restrain the setting of plaster, etc.*

It is composed essentially of animal gelatinous or vegetable glutinous matter and hydrated lime.

409012—August 13, 1889. M. B. Church. *Ornamentation of walls.*

A fatty matter such as oil or glycerine is added as a retarder to alabastine, a mixture of calcined gypsum and glue.

422171—February 25, 1890. G. West. *Composition of matter for architectural purposes.*

A compound of glue and sal soda to be used with plastering material.

422269—February 25, 1890. G. West. *Plastering compound.*

A compound of glue, dextrin, and sal soda to be used with plastering material.

422270—February 25, 1890. G. West. *Composition of matter for architectural purposes.*

It consists essentially of glue or other well-known retarder and boracic acid.

427591—May 13, 1890. R. B. and E. H. Martin. *Wall-covering composition.*

Citric acid is used as a retarder.

433743—August 5, 1890. S. S. Ruston, W. E. Hopkins, and B. Ruston. *Process of manufacturing plastering compounds.*

A dry pulverulent restraining compound is produced by dissolving the restraining substance in water, and mixing therewith a dry, absorbent, comminuted material, by stirring under the application of heat, until it is converted to a dry, pulverulent state.

433899—August 5, 1890. H. Leichsenring. *Artificial plaster.*

It consists of glycolline, plaster of Paris, and water.

437140—September 23, 1890. J. Sickler. *Process of calcining gypsum.*

The retarding agent is incorporated with the plaster during the process of calcining, and while it is in a molten condition and prior to complete calcination.

445211—January 27, 1891. E. Watson. *Composition of matter for retarding the setting of plaster.*

Hair is boiled with an alkali, caustic soda or potash, and used in liquid form, or evaporated and reduced to a powder.

446604—February 17, 1891. E. Watson. *Composition of matter for restraining the setting of plaster compounds.*

A dry leguminous substance, such as peas, beans, lentils, etc., treated with a solution of caustic alkali, mixed with an alkaline earth or a salt of an alkaline earth, or a salt of a caustic alkali, dried and pulverized.

452346—May 12, 1891. I. C. Hart. *Plastering compound.*

Lime is dry slaked with glue water.

456297—July 21, 1891. A. Anthony. *Plastering composition.*

Uses as a retarder in a specified plastering composition a submixture of sugar, slaked lime, and bicarbonate of soda.

458742—September 1, 1891. E. Watson. *Composition of matter for restraining the setting of plaster.*

A mixture of flaxseed or oil meal cake and an alkali, as carbonate of soda or potash, is reduced to a dry powder.

458743—September 1, 1891. E. Watson. *Composition of matter for restraining the setting of plaster.*

Comminuted hoof, horn, or feathers is dissolved by boiling in a solution of caustic alkali, dried, and reduced to a powder.

462678—November 10, 1891. G. W. Abell. *Composition of matter for wall coverings.*

A mixture of white lead, litharge, sugar, linseed (oil cake) meal, lime, calcined gypsum, sand, and water, in specified proportions.

465614—December 22, 1891. G. E. Coy. *Compound to restrain the setting of plaster, and process of making the same.*

A mixture of pulverous quicklime, glue, and flour.

469394—February 23, 1892. G. W. Abell. *Composition of matter for covering walls or other surfaces.*

A mixture of dry oxide of zinc, sugar, flour of sulphur, wood pulp, linseed (oil cake) meal, ground gypsum, lime, sand, and water in specified proportions.

472322—April 5, 1892. E. Watson. *Composition for retarding the solidification of calcined gypsum.*

It consists essentially of calcined gypsum and "tank water;" to retard the setting from half an hour to three hours or more, from 2 to 10 gallons to a ton of calcined gypsum, or of the semisolid substance, stick, from 2 to 10 pounds to the ton, or from 5 to 15 pounds of dry material, formed by mixing any earthy substance, siliceous or aluminous, with tank water and drying and pulverizing.

472511—April 5, 1892. W. Robinson. *Wall plaster.*

A mixture of sand, plaster of Paris, glue, lime, clay, alum, and starch.

478951—July 12, 1892. C. Cassteel. *Plaster.*

A composition consisting of water, lime, gypsum, and coke, or brick dust, with a small proportion of a mixture of sugar, alum, and lime as a retarder.

479060—July 19, 1892. E. W. Dickie. *Composition of matter for plastering.*

A mixture of sand, plaster of Paris, shell marl, and cut rope, or hair, with glue, alum, and sulphate of zinc as a restrainer, combined in a specified manner and proportions.

485177—November 1, 1892. C. L. Denison. *Wall plaster.*

A composition consisting of lime, cottonseed meal, plaster of Paris, borax, and cream of tartar.

493613—March 14, 1893. E. A. Bronson. *Compound for retarding the setting of cement.*

It is composed of air-slaked lime, glue, flaxseed, or oil cake, and china clay, in specified proportions.

502096, 502097—July 25, 1893. T. J. Heller. *Plaster composition.*

A compound for admixture with a plaster composition consisting of silicate and carbonate of soda, alum, sugar, gum, salt cake, and ground inert material.

503592—August 22, 1893. J. Flynn. *Composition for architectural purposes.*

The retarder, combined with other ingredients, consists of a solution of carbonate of potash and glue absorbed in quicklime.

504933—September 12, 1893. E. A. Moore. *Composition for architectural purposes.*

A mixture of dry pulverous glue, sulphuric acid, kerosene oil, and quicklime, as a retarder, is combined with sand, raw gypsum, and lime.

507942—October 31, 1893. B. D. Stafford. *Composition for plaster and coating walls.*

It consists of powdered borax, powdered alum, wheat flour, powdered sugar, and dry slaked lime in specified proportions.

511735—December 26, 1893. J. K. Jones. *Wall plaster.*

The retarder is composed of sugar, 100 parts; flour, 25 parts; and air-slaked lime, 250 parts.

511740—December 26, 1893. J. R. McIlvried. *Process of manufacturing retarders for plaster.*

A paste is formed of air-slaked lime, water, flour, liquid glue, and wood ashes, dried and thoroughly mixed.

511879—January 2, 1894. W. M. Dawson. *Plastic compound and process of making same.*

The restrainer consists of a mixture of lime with the liquor obtained by the decomposition of organic matter in water.

523658—July 31, 1894. W. M. Dawson. *Plastering retarder and method of making same.*

The restrainer consists of a mixture of lime, sodium nitrate, and the liquor obtained by the decomposition of organic matter in water.

528995—November 13, 1894. A. W. Smith. *Plastering compound.*

The restrainer consists of lime, glue, wheat flour, and tartaric acid in certain proportions.

533420—February 5, 1895. W. H. Aikman. *Building plaster.*

As an ingredient of building plaster, a compound of alum, wheat flour, sugar, lime, oil cake meal, and zinc sulphate in specified proportions.

554142—February 4, 1896. W. M. Reese. *Plaster.*

A mixture of pulverized gypsum and dry tankage in the proportions of 10 pounds of tankage to a ton of gypsum, is calcined and the heat continued to a temperature of 380° to 420° F.

558435—April 14, 1896. J. E. Summers. *Plastering compound.*

A mixture of furnace slag, slaked lime, plaster of Paris, hydraulic cement, the flour of grain, and vegetable fiber in specified proportions.

619911—February 21, 1899. H. E. Sturcke. *Manufacture of plaster and restrainers.*

The restrainer consists essentially of the pulverized residue of an evaporated solution of bone in alkali.

PHOSPHATE ROCK

PHOSPHATE ROCK.

By Joseph Struthers, Ph. D.

Prior to the report of 1880 no figures relating to the production of phosphate rock appeared in census reports. In that year 21 establishments were reported in South Carolina, with a product of 211,377 tons, valued at $1,123,823. At the Eleventh Census the production for 1889 was shown, and the totals, compared with those for 1902, appear in Table 1.

Table 1.—*Comparative summary: 1902 and 1889.*

	1902	1889
Number of mines or quarries	115	[1]
Number of operators	87	[1]
Salaried officials, clerks, etc.:		
Number	391	[2]
Salaries	$355,204	[2]
Wage-earners:		
Average number	5,971	[3]5,011
Wages	$1,930,093	[4]$1,209,151
Contract work	$157,402	$115,930
Miscellaneous expenses	$430,475	$343,271
Cost of supplies and materials	$799,414	$317,159
Product:[5]		
Quantity, long tons	1,548,720	550,245
Value	$4,922,943	$2,937,776

[1] Not reported.
[2] Not reported separately.
[3] Includes foremen.
[4] Includes salaries of office force.
[5] The United States Geological Survey reports 1,490,314 short tons, valued at $4,693,444, which is the product marketed. The Census figures represent the product mined.

The most notable fact in the industry is the transfer of dominance from South Carolina to Florida. During the period between 1889 and 1902 the production in Florida increased nearly one hundredfold in quantity and over sixtyfold in value; at the same time that of South Carolina decreased 39.5 per cent in quantity and 67.1 per cent in value. The increase in Florida was due chiefly to the exportation of phosphate rock which is easily mined near tide water. Tennessee did not produce any rock in 1889, but in 1902 the production of the state was 432,603 long tons, valued at $1,308,872. This rock, however, was of low grade, averaging in value only $3.03 per ton. North Carolina did not report any product in 1902 and in 1889 its production reached a total valuation of only $5,000. By the growth of the industry in Florida and in Tennessee the production for the United States as a whole increased 181.5 per cent in quantity and 67.6 per cent in value.

Among the most significant items of Table 1 are those relating to wage-earners and their earnings. By this table it appears that the number of salaried officials, clerks, etc., and wage-earners increased 1,351, or 27 per cent, while the amount paid in salaries and wages increased 89 per cent. The number of boys employed was not large in either year, and although the industry increased in all other respects, the number of boys decreased from 91 to 37, or 59.3 per cent. In South Carolina, where 90 boys were employed in 1889, none were reported in 1902. The figures in Florida in 1889, however, do not offer a wholly satisfactory basis upon which to make comparisons. Mining operations had been recently begun, and the industry was in a condition of speculative excitement.

There were 19 mines in Florida, South Carolina, and Tennessee reported idle during 1902, and 2—1 each in Florida and North Carolina—at which development work was reported. The statistics for the development work at these 2 mines are shown in the following statement:

Development work: 1902.

Number of mines	2
Number of operators	2
Salaried officials, clerks, etc.:	
Number	4
Salaries	$4,315
Wage-earners:	
Average number	5
Wages	$1,323
Miscellaneous expenses	$666
Cost of supplies and materials	$726

Capital stock of incorporated companies.—The details of the capitalization of the 56 incorporated companies are shown by states in Table 2:

TABLE 2.—*Capitalization of incorporated companies: 1902.*

Interest paid	$61,750	$55,510	$3,240	$3,000	.....

[1] Includes companies distributed as follows: Arkansas, 1; Ohio, 1.

The total amount of common and preferred stock issued amounted to $12,321,135. On this amount $316,205 was paid in dividends, or 2.6 per cent on the total par value. On the bonded indebtedness $61,750 was paid as interest. This was 4.3 per cent of the par value of the amount issued. In Tennessee the dividends on common stock amounted to 2.7 per cent, and those on preferred stock to 6 per cent on the respective par values of the stock issued. In Florida, with a capitalization quite similar in amount, dividends were paid on common stock at the rate of 1.5 per cent, and on preferred stock at the rate of 15.2 per cent.

Employees and wages.—The average number of wage-earners reported for each month in Table 6 shows that the demand for labor was relatively steady throughout the year. In the South the climate is favorable to the continuous working of deposits. Between September, for which month 6,442 wage-earners, the maximum number, were reported, and February, when 5,366 wage-earners, the minimum, were at work, there is a variation of only 1,076. The average per month for the year was 5,971 wage-earners. Child labor constituted six-tenths of 1 per cent of the total, and was confined mostly to the small colored boys who drove carts. Florida employed 48 per cent of the total number of wage-earners; South Carolina, 25.1 per cent; Tennessee, 26.7 per cent; and all other states, two-tenths of 1 per cent.

A segregation of the occupations in this industry by specified daily rates of pay is shown in Table 3.

TABLE 3.—*Average number of wage-earners by specified daily rates of pay: 1902.*

RATE PER DAY (DOLLARS).	All occupations.	Engineers.	Firemen.	Machinists, blacksmiths, carpenters, and other mechanics.	Miners or quarrymen.	Timbermen and track layers.	Boys under 16 years.	All other wage-earners.
Total	5,971	173	169	171	4,382	111	37	928
Less than 0.50	52	.....	.....	.....	.....	.....	7	45
0.50 to 0.74	89	.....	.....	1	6	.....	27	55
0.75 to 0.99	1,288	.....	14	20	1,010	10	2	232

2.25 to 2.49	33	24	1	7	1	.....	.....	.....
2.50 to 2.74	55	20	4	29	2	.....	.....	.....
2.75 to 2.99	3	1	.....	.....	2	.....	.....	.....
3.00 to 3.24	21	11	.....	6	4	.....	.....	.....
3.50 to 3.74	4	2	.....	1	1	.....	.....	.....
3.75 to 3.99	3	.....	.....	1	2	.....	.....	.....
4.00 to 4.24	5	2	.....	1	2	.....	.....	.....
4.25 and over	8	1	.....	5	2	.....	.....	.....

Of the wage-earners, 1,429, or 23.9 per cent of the whole, received less than $1 per diem, and 5,085, or 85.2 per cent, less than $1.25. Only 233, or 3.9 per cent, received $2 or more per diem. Of the wage-earners in Florida 5.9 per cent received $1.75 or more per diem, while in South Carolina the corresponding percentage was 3.9. In Tennessee only 1.9 per cent received $1.75 or more.

Mechanical power.—The primary power reported for this industry aggregated 14,229 horsepower, all owned by the operators reporting, distributed as follows: 282 steam engines with a horsepower of 13,974, 1 water wheel of 170 horsepower, and 2 air compressors of 85 horsepower. There were also 9 electric motors with 500 horsepower.

Production.—The quantity and value of the production of phosphate rock, beginning with 1889, are shown in Table 4.

TABLE 4.—*Production of phosphate rock: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

YEAR.	Quantity (long tons).	Value.
1889	550,245	$2,937,776
1890	510,499	3,213,795
1891	587,988	3,651,150
1892	681,571	3,296,227
1893	941,368	4,136,070
1894	996,949	3,479,547
1895	1,038,551	3,606,094
1896	930,779	2,803,372
1897	1,039,345	2,673,202
1898	1,308,885	3,453,460
1899	1,515,702	5,084,076
1900	1,491,216	5,359,248
1901	1,483,723	5,316,403
1902	1,490,314	4,693,444

During this period the quantity of production has increased 170.8 per cent. The greatest amount produced in any one year was 1,515,702 long tons in 1899. In 1889 the average value per ton was $5.34, while in 1902 it was $3.15. The production of phosphate rock in the world, from 1896 to 1901, is given in Table 5.

TABLE 5.—WORLD'S PRODUCTION OF PHOSPHATE ROCK: 1896 TO 1901.

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

[1] Cubic meters. [2] Statistics not yet available. [3] Value not reported.

The detailed statistics of the industry for 1902 are given in Table 6.

DESCRIPTIVE.

The name phosphate is applied to the salts of phosphoric acid, chiefly "orthophosphoric" acid, which is a tribasic acid (H_3PO_4) and from which a great variety of salts are obtained. Each of the three hydrogen atoms in the acid can be replaced by a monad element, forming, consequently, three varieties of salts, namely, those in which one hydrogen atom is replaced, those in which two hydrogen atoms are replaced, and those in which all of the hydrogen atoms are replaced. Salts in which all of the hydrogen atoms have been replaced are called ortho or neutral phosphates, while those still containing one or two atoms of hydrogen are called acid phosphates. Calcium phosphate, or, more strictly speaking, tricalcium orthophosphate, is the most important of the mineral phosphates and this class forms the large mineral deposits utilized for the manufacture of fertilizers.

Historical.—According to historical records, the Romans utilized the excrement of birds for fertilizing the soil, and in the twelfth century the Arabs and Peruvians used the guanos of their respective countries for a like purpose.

The waste clippings of bone and ivory from the button and knife factories of Sheffield, England, greensand from the counties of Kent and Essex, England, marls from the state of New Jersey, and boneblack (spent animal charcoal) and crushed bones were used as fertilizers at different times during the eighteenth and nineteenth centuries, but while the beneficial results from their use were recognized and appreciated, the real cause of the stimulating effect seems not to have been definitely recognized until Dr. Justus von Liebig, of Geissen, Germany, evolved the idea that sulphuric acid should be added to bone fertilizers in order to render soluble the phosphate they contained. It was not until the year 1843 that the Duke of Richmond, after an exhaustive series of experiments upon the soil with both fresh and degelatinized bones, came to the conclusion that their value for fertilizing purposes was due to the large quantity of phosphoric acid contained in them. To prove this effect a number of vegetables were planted in burnt sand rich in every element of fertility except phosphoric acid; no development of the plant took place until calcium phosphate had been added to the sand, but after this addition the growth became flourishing.[1]

The calcium phosphate in bones had hitherto been considered as useless owing to its insolubility, and the fertilizing element was considered to be the gelatinous matter. Shortly after 1840 Mr. J. B. Lawes put Doctor von Liebig's ideas into practice, and began to manufacture artificial fertilizers at Deptford (London), England, by mixing sulphuric acid with crushed bones. In the year 1845 Professor Henslow recommended that the Cambridge coprolites, rich in calcium phosphate, should be used as a substitute for bones in making fertilizers, and, acting on this suggestion, the numerous bone crushing works were quickly converted into chemical fertilizer and superphosphate factories. The coprolites of Cambridge were supplemented by the phosphate deposits in Suffolk and Bedfordshire, but it was not until twenty-five years later that the phosphate mining industry began to assume a commercial importance. This slow growth is attributed to the immense supply of guano obtained from Peru, the best beds of which did not become exhausted until between 1870 and 1875; the failure of this source of supply immediately led to the substitution of other material for the manufacture of fertilizers.

Occurrence.—In France the phosphate deposits at

[1] Phosphates of America, by Francis Wyatt, Ph. D., page 19.

Grand Pré, in the Ardennes, began to be exploited in 1856, and small quantities of the rock in a ground state were utilized by direct addition to the soil. In 1865 other deposits were discovered on the plateau of Quercy, in the department of Lot, and in 1870 the deposits of Lot-et-Garonne, Tarn-et-Garonne, and Aveyron (known as the Bordeaux phosphates) were mined and the product sold to fertilizer manufacturers. In Spain the mining of phosphate rock began at Logrosan, province of Estremadura, about the year 1855, followed, in 1860, by the exploitation of the deposits near Caceres, the latter district yielding a considerable quantity annually until 1875. In Norway phosphate deposits were mined at Kragerö, in 1854, and at Oedegarten, in 1874. In Germany the Nassau phosphate deposits were discovered in 1864 and the mining of the rock commenced at once. In recent years the competition in the world's markets of higher grade and purer phosphates from other countries has caused the cessation of the exports of rock from the Lahn mines, the material of which contains a large percentage of iron and aluminum oxides. In a few of the islands of the West Indies, notably Navassa and Sombrero, prior to 1865 phosphate deposits had been opened and the product shipped to the United States and the United Kingdom.

In the United States deposits were first worked in South Carolina in 1867. From 1867 to 1877 there was a great advance in the world's production of phosphate rock. In 1873 Belgium began contributing to the world's supply from the deposits near Mons, and France increased its production very largely. In 1880 the islands of Curaçao and Oruba, in the Dutch West Indies, supplemented the output of high-grade phosphates and shipped an average of 10,000 tons for the year.

In the decade 1880 to 1890 the sources of the supply of phosphate rock altered very considerably. At the end of this period Spain, which in 1882 and 1883 shipped 100,000 tons to the United Kingdom, practically ceased to export. In France the old sources of supply had been replaced to a large extent by the newer fields in the Somme and other departments in the north. Belgium had assumed an important place, producing about 150,000 tons of phosphate from the mines at Mons alone. In the United States the South Carolina deposits had been developed to a very large extent and Florida had begun to contribute appreciably to the supply.

Characteristics and use.—The various deposits of phosphatic material have not yet been classified geologically owing to the difficulty in determining the position of several of the deposits, augmented by the large number of forms which the phosphate assumes and the complex blending of certain varieties. The common technical classification makes the broad distinction between mineral phosphates, whose origin can not be traced to animal life, and rock phosphates, more or less mineralized, but directly traceable to an organic origin. On this basis the only mineral phosphates are those containing crystalline apatite, which occur in Canada, Norway, and a few localities in Spain. The deposits at Nassau in Germany, Lot-et-Garonne, Tarn-et-Garonne, and Aveyron in France, and Logrosan and Caceres in Spain are usually included in the mineral phosphates under the arbitrary and indefinite term "phosphates." The term rock phosphates includes the remaining varieties of phosphatic limestone, coprolites, nodular phosphates, concretionary phosphates, arenaceous phosphates, sheet-rock phosphates, and bone beds.

The value of phosphate rock in the United States lies solely in its use as a fertilizer to enrich land impoverished by continual removal of crops that have grown thereon, or land which did not originally possess the components necessary for the normal growth and development of plant life.

It has been only within comparatively recent years that the relation between plants and soils has been scientifically studied. In general the manner of life in plants resembles that of animals or man, in that they require certain foods in stated proportions which are digested or assimilated, they must breathe a certain atmosphere, and they are subject to the influence of heat and cold, light and darkness. The tissues of plants, like those of animals, are composed of carbon, hydrogen, oxygen, nitrogen, and certain mineral acids or bases, notably phosphoric and sulphuric acids, lime, magnesia, iron, and potash; and the growth of a plant bears a close relation to that of an animal for the reason that it constantly absorbs elements from the soil and air to build up its structure. The relation of plant life to animal life is reciprocal. Animals breathe in the oxygen of the air and convert a small part of it into carbon dioxide, which is exhaled and returned to the air, while plants, under the action of chlorophyl and sunlight, absorb carbon dioxide from the air and decompose it into carbon and oxygen, utilizing the former to build up the cellular structure and returning the oxygen to the air. The chief elements assimilated by plants, and consequently removed from the soil when the plants are cut down and taken away, are nitrogen, phosphoric acid, and potash. These compounds play a very important part in the functions of vegetation and are the most liable to be exhausted from the soil. The estimated mean annual quantity and value of a few of the important vegetable products in the United States have been compiled as follows:[1]

[1] Phosphates of America, page 14.

Estimated mean annual quantity and value of certain vegetable products in the United States.

	Average percentage of ash or mineral.	Quantity (bushels).	Value.
Wheat	2.06	450,000,000	$440,000,000
Maize	1.55	1,900,000,000	627,000,000
Oats	3.18	600,000,000	168,000,000
Potatoes	3.77	200,000,000	100,000,000
Hay	7.24	[1]45,000,000	360,000,000
Cotton	3.10	[2]6,500,000	250,000,000

[1] Tons. [2] Bales (480 pounds).

According to Wyatt, the total weight of the ash contained in the entire annual cereal production of the United States (wheat, maize, oats, barley, rye, and buckwheat), about the year 1890, exceeded 17,500,000,000 pounds, containing 2,714,585,473 pounds of phosphoric acid.[1] Of course, a large part of the phosphate content of the plants was returned to the soil in one form or another, but the annual loss to the soil was nearly 1,500,000 pounds of phosphoric acid.

As the area of cereal production at that time was 140,378,857 acres, these figures show that the quantity of phosphoric acid removed annually by the cereal crop is approximately 19 pounds per acre. Similarly, the quantity removed by the hay crop is calculated to be 12.5 pounds per acre. Further, it has been shown that every cow kept on pasture land carries off during a summer not less than 50 pounds of calcium phosphate in the shape of veal, butter, and cheese.[2]

These few instances show in a striking manner the enormous loss of phosphoric acid occurring in agricultural districts, and the necessity of returning to the soil those salts which have been removed therefrom.

REVIEW OF THE INDUSTRY IN THE UNITED STATES.

The phosphate deposits of the United States are described by states as follows:

Florida.—Phosphate rock occurs over a large area, extending from Lake Okeechobee on the south to the extreme northern part of the state—a distance of 240 miles, and averaging 30 miles in width. The deposits of commercial value, however, are comparatively few in number and are widely scattered throughout the region. The three chief classes of the phosphate rock product in the order of importance are hard rock, land pebble, and river pebble.

Hard rock is mined in an area of 90 by 10 miles, extending from Albion on the north to Bay City on the south. The material is obtained from pockets which vary in yield from a few tons to many thousands, and run so irregularly that it is frequently necessary to change the location of the mining plants. In former times the mining operations were limited solely to the bowlders of phosphate rock, which varied in weight from a few pounds to many tons. The mining consisted in removing the rock from the pits, drying it in the kilns, and shipping it without any additional preparation. Little capital was called for, and many hard-rock companies were formed to mine the rock, but they finally withdrew from business on account of the scarcity of deposits easy of extraction. Attention was then directed to mining the gravel phosphate, which represents the smaller or broken pieces of the bowlders that occur intermixed with clay, flint, etc., the sterile material being removed by washing in the ordinary log washer. Later, as the mining and milling processes became more complicated and costly, large central plants were erected for cheaper treatment cost, but the economies sought, however, were not realized, on account of the small size of the individual deposits and the consequent expense of transporting the crude material containing less than 15 per cent tricalcic phosphate from the mines to the mill.

At the present time the cheapest method of treatment is to have one or more removable washing plants, each of a capacity of from 40 to 50 tons of clean rock in twelve hours. These plants are so constructed that they can easily be taken down and removed to new localities. It is also the present practice to crush, wash, and screen the entire product of the mine.

The most recent practice in mining hard rock is the installation of dredges of the dipper type to mine deposits that have been worked down to the water level, particularly in those cases where it has been found impracticable to handle the water with pumps. The use of the dipper dredge is economical, and with deposits that can be handled by this method very excellent results have been obtained, so much so that deposits unworkable at a profit by the older methods of mining are now treated with commercial success, the clay, sand, and fine material being removed in log washers plentifully supplied with water. The washed rock is carefully hand picked on a picker belt, dried in kilns, which consume from 5 to 7 cords of wood per 100 tons of rock, and is then ready for shipment to market.

The average cost of production, f. o. b. at the mines during 1900 was from $3.50 to $4 per ton. According to C. G. Memminger those deposits most favorable for cheap transportation and mining are almost exhausted, and the present efficient methods of mining and handling leave but little room for diminishing the cost, consequently with the gradual exhaustion of the best

[1] Phosphates of America, page 15.

[2] United States Geological Survey, Bulletin 46, "Nature and Origin of Deposits of Phosphate of Lime," by R. A. F. Penrose, Jr.

deposits the cost of production must increase. It is quite probable that the cost of production of from $3.50 to $4, f. o. b. at the mines, is as low as it ever will be. The cost to the consumer, however, is regulated largely by the cost of transportation from mines to port of shipment.

Hard rock is sold on a guarantee of a minimum of 77 per cent tricalcic phosphate (bone phosphate of lime) and a maximum of 3 per cent iron and aluminum oxides. Practically the entire output is exported, chiefly to Germany. The ports for shipment of hard rock are Fernandina, Port Inglis, and Tampa, Fla., and Brunswick and Savannah, Georgia.

The land pebble phosphate rock occurs in Polk, De Soto, and Hillsboro counties, Florida, occupying an area of about 2,000 square miles, beginning a few miles north of Bartow and extending over the upper portion of the drainage basin of the Peace and Alafia rivers. During the past few years the entire product has been obtained from Polk county. The area of the occurrence of land pebble is restricted and the deposits widely scattered, rendering this branch of the industry of comparatively less importance than the others, yet several hundred thousand tons of phosphate may be obtained from a single deposit. The pebbles are roughly rounded, of a gray or brownish color, and vary in size up to two inches in diameter. In preparing the material for the market two classes of product are made, the size of the coarser being from one-sixteenth to 1 inch in diameter. The deposits are usually along the stream courses, in low swamps, or in bay heads. The thickness of the deposits varies from a few inches to 18 feet, averaging 10 feet for the district. The pebble, which usually represents less than 25 per cent of the mass, occurs in an argillaceous matrix, sometimes very sticky and tenacious, and sometimes sandy and readily disintegrated; the overburden consists of sandy soil, clay, and a so-called conglomerate rock of varying character in different parts of the deposit. The bed rock varies from a hard yellow marl to a soft, clay-like material. The highest grade of land pebble contains from 68 to 73 per cent of tricalcic phosphate and from 3 to 4 per cent of iron and aluminum oxides; the low-grade material has from 60 to 65 per cent of tricalcic phosphate and from 4 to 5 per cent of iron and aluminum oxides. At the present time land pebble is sold on a guarantee of a minimum of 68 per cent of tricalcic phosphate and a maximum of 4 per cent of iron and aluminum oxides; conditions which, in order to operate at a profit, call for an average yield of 20 per cent of pebble to the mass, an average minimum thickness of 8 feet of the deposit (yielding 3,733 tons to the acre), and an overburden not exceeding the thickness of the deposit.

Within recent years a hydraulic method of treating land pebble has been devised, which is undoubtedly the only practical method of handling this class of material. The important feature of the process is that the water which is used to break down the rock also partially disintegrates the matrix and renders the succeeding washing for the separation of the pebble a very simple operation. According to C. G. Memminger the equipment of a hydraulic plant consists of a steam shovel for removing the overburden, one or more dredges fitted with boilers of from 400 to 500 horsepower, a 10-inch centrifugal pump, hydraulic-pressure pumps, screens and washers, and barges to carry the pebble to the mill. The mill should contain a sufficient number of washers, rotary driers, elevators, boilers, and dry-storage bins of from 4,000 to 15,000 tons capacity—an equipment which calls for a heavy investment. A plant with one dredge and two driers should produce 50,000 tons of pebble per year. The method of mining is briefly outlined as follows: The overburden having been removed by the steam shovel, the dredge is launched in a suitable excavation and the suction pipe from the centrifugal pump on the dredge is laid some 150 feet in advance, where a small sump hole is opened for suction. Streams of water from two hydraulic giants, working under a pressure of from 100 to 110 pounds per square inch, are directed into the hole, which is increased to a considerable size in a short time. The suction gradually becomes lowered until the sump is formed in the bed rock. As soon as possible the giants are placed in the pit, and as the banks are cut down the material passes with the water to the sump and is pumped to the dredge, where it is screened, the pebble being thoroughly washed and separated and the débris discharged at the side of the dredge. As the pit becomes enlarged it is a good practice to use a second centrifugal pump in connection with the pump on the dredge. In this way a pit of several acres in extent can be mined. The pump and pipes are removed from the pit as soon as economy in pit size is reached. The pit is filled with water and the bank between the dredge and the pit is broken. The dredge is then moved on and operations begin afresh. The pits form a channel for the transportation of the pebble in barges. On reaching the mill the pebble is elevated, thoroughly washed, dried, and stored for shipment.

The most modern plant in this district has been equipped with electric motive power, the intention being to eliminate the dredge by using a series of electrically-driven centrifugal pumps which will force the entire material mined to the mill, a central pumping station giving the hydraulic pressure required. Under certain conditions this system promises excellent results.

An innovation at the works of one of the phosphate companies is the installation of a central plant to generate electric and hydraulic power for the mining operations. The results have proven eminently successful and under proper conditions the method promises to supersede the older and less economical ones.

The highest grade deposits with light overburden

and greatest yield per acre are fast being exhausted, and fuel, which is a large item of cost, is rapidly being exhausted in the vicinity of the mines. The question of fuel supply is one of great importance in connection with the future of the industry. Large tracts of woodland have been bought up by the various companies, but wood will undoubtedly be supplemented by coal when the mines control the transportation to the point of shipment. Fuel oil also will become a possible substitute for wood under the new conditions of transportation.

The present cost of production, f. o. b. at the mines, is from $1.50 to $2 per ton, a figure that will doubtless increase very materially in the near future. The product is shipped from Port Tampa. At the present rate of production the deposits containing 68 per cent and upward of tricalcic phosphate, and low in iron and aluminum oxides, will be exhausted within a few years. Those containing from 64 to 67 per cent tricalcic phosphate and from 4 to 6 per cent iron and aluminum oxides are in very large reserves. There has been a marked tendency toward more careful methods in the preparation of the rock for the market, which is attained usually by installing one or more log washers in addition to the ordinary double log washer plant; and by crushing the rock after it has been dried, and subsequently screening it, this procedure has been productive of good results with certain classes of rock.

As the higher grade deposits become exhausted the methods of treatment must be improved in order to handle the lower grade rock at a lessened cost. As a proof of the growing scarcity of the best class of rock, deposits having an overburden of from 25 to 30 feet are now being opened up and developed. Deposits of this character a short time ago were declared unsuited for profitable working.

The excessively high transportation and terminal charges prevailing in recent years have forced miners to seek relief. One company has constructed a private railroad from the central plant at Rockwell to Port Inglis, 18 miles distant, at the mouth of the Withlacoochee river. The port is an open roadstead, and the vessels have to be loaded by lighters.

As in the case of the hard-rock miners, there have been several unsuccessful efforts to consolidate the large miners of land pebble into a community of interests, which would eliminate useless competition and enable the producers to maintain prices at a level which would admit of mining at a fair profit.

The bulk of the river pebble has been obtained from Peace river, which rises near Bartow and flows 200 miles in a southerly direction into Charlotte harbor. The Alafia river, a small stream flowing into Tampa bay, has also contributed a small quantity of river pebble, and the Caloosahatchee, Miakka, and Manatee rivers have produced a pebble of low grade.

The method of mining the river pebble consists in using dredging boats equipped with 8-inch or 10-inch centrifugal pumps, to which are attached suction pipes suspended from cranes. The pebble, being loosely mixed with sand, is readily raised by the pumps and passed into a rotary screen, which separates the sand and delivers the washed pebble onto a lighter moored alongside the dredge. When a sufficient quantity of pebble has accumulated on the lighter, it is carried to the drying plant, dried in rotary calciners, and stored in bins, from which it is finally discharged by gravity directly into cars for shipment. As the supply of pebble in the river beds became exhausted, attention was given to the deposits lying under the swamps which were formed by the river at an earlier period. Generally these deposits are covered with an overburden of sand of from 5 to 15 feet in thickness, supporting a thick growth of heavy timber. In order to obtain the river pebble from the swamp deposits the timber was removed and the overburden washed into the stream and removed by pumps; later the pebble was obtained in like manner and treated similar to the pebble in the river beds.

The total production of phosphate rock of all classes in Florida, as reported by the United States Geological Survey, based on marketed output from 1888, the year of the inception of the industry, to and including 1902, aggregates 6,606,468 long tons, valued at $24,667,099.

South Carolina.—Although the phosphate deposits in South Carolina had been known for many years, they were not recognized as such prior to the Civil War. A mining company was formed in 1867 to test the practicability of working the phosphate rock on a commercial scale. The phosphate "belt" is composed of Quaternary sands and clays overlying beds of Eocene marls upon whose surface, and intermixed with it, are found the phosphate deposits. The presumed total area of the phosphate formation is 70 by 30 miles, extending from the mouth of the Broad river, near Port Royal on the southeast, to the headwaters of the Wando river in the northeast, its major axis being parallel to the coast line and its greatest width near Charleston. The stratum of phosphate rock sometimes outcrops at the surface, but it is generally found at a depth of from 3 to 20 feet and varies in thickness from a few inches up to 3 feet. The chief points for consideration in order to ascertain the value of the phosphate beds are thickness of deposit, depth below the surface, and richness in phosphoric acid.

In South Carolina the general method of ascertaining the value of a phosphate rock deposit is by means of boring and pit sinking. At first a careful topographical survey of the property is made, followed by the systematic sinking of a series of bore holes by means of a long steel borer or rod specially designed for the purpose. The boring rod is forced downward through the upper strata until it strikes the solid bed of phosphate rock, which makes itself evident by resisting the further passage of the rod. The rod is then removed, and the distance it has traversed is measured with a

foot rule, thus showing the thickness of the overlying strata. The rod is replaced in the bore hole, forced through the resisting stratum, and again withdrawn and measured, the difference between the first and second measurements being taken as representing the thickness of the phosphate bed. The bore holes are generally 100 feet apart, extending over the entire area of the land under examination. A series of exploring pits 10 feet long and 5 feet wide are dug at 500-foot intervals in order to verify and confirm the results obtained by the bore holes. The phosphate rock is carefully removed, the depth from the surface and the thickness of the bed is measured, and average samples of the rock and nodules are obtained for analysis. Throughout the area of the South Carolina field the strata overlying the phosphate rock are remarkably uniform. Heretofore, mining operations have been limited to material occurring not more than 15 feet from the surface, but there are larger areas containing phosphate rock at a greater depth than 15 feet whose value has not yet been determined.

The phosphate deposits of South Carolina are classified into river rock and land rock, the river rock, which is found in the beds of rivers, having been washed into them from the original land beds.

The river rock has been worked extensively and with considerable profit, for the reason that it is obtained by the simple and cheap process of dredging, which at the same time washes the rock free from adhering impurities. The dredging scoops are massive in construction in order to break through the stratum containing the nodules of phosphate rock. The boats are held in position by four "spuds," or strong, square iron-tipped poles, one at each corner. The nodules are thrown from the scoop into the washer which is generally on a lighter moored alongside of the dredge. Various kinds of washers are used, the one in common practice consisting of a truncated iron cone with perforated sides revolving on a horizontal axis and furnished on the inside with steel spirals like the grooves in a rifle barrel. The nodules are dumped by the dredge into the small end of the cone, heavy streams of water are introduced through both ends and the cone rotated; the washed material is discharged at the larger end of the cone and is removed by a derrick to another boat which carries it to the shore. The dredge generally used is of the ladder bucket type, which consists of a series of steel buckets connected by means of double links, the whole forming an endless chain which moves over drums or tumblers fixed at the ends of the ladder or frame. The higher end of the ladder is placed directly above the receiving hoppers and the lower end is supported by a tackle which allows it to be raised or lowered, according to the depth at which the work has to be done. The motive power is applied at the upper end by means of friction gear, so that any undue strain will not break the machinery. The ladder bucket dredge in the phosphate field ordinarily does not operate at depths greater than from 20 to 25 feet. Occasionally, for depths greater than 20 feet and up to 50 and 60 feet, a clam-shell bucket dredge is used, consisting of a contrivance of 4 or 6 iron claws which open as they are lowered and close forming a bucket as they ascend. The bucket, generally of about 1 cubic yard capacity, is operated from a swinging crane covering a radius of 25 feet in front of the scow; the material is delivered at a height of 14 feet above the deck into the receiving hoppers which feed into the washers. The cost of operating a clam-shell bucket dredge is from four to five times that of the ladder bucket dredge.

Both the rock and nodules from the river and land deposits occur in very irregular masses or blocks of extremely hard conglomerate of variegated colors, which weigh from half an ounce up to more than a ton.

The mean specific gravity of the material is 2.4, and the rock is perforated with a network of very small holes, the work of innumerable crustacea, now filled with sands and clays from the overlying strata. Sometimes the nodules are quite smooth or even glazed as if worn by water; in other cases they are rough or jagged.

The average analysis of South Carolina rock may be taken as follows:

		Per cent.
Tricalcic phosphate	$Ca_3(PO_4)_2$	59.63
Calcium carbonate	$CaCO_3$	8.68
Magnesium carbonate	$MgCO_3$	0.73
Iron and aluminum oxides	Fe_2O_3 and Al_2O_3	6.60
Sulphuric acid Calcium fluoride	H_2SO_4 CaF_2	4.80
Water and loss on ignition	H_2O	8.00
Silica and undetermined	SiO_2	11.56

The land rock occurs chiefly in the vicinity of Charleston, while the river rock is confined to the Coosaw river and other streams in the vicinity of Beaufort. The land rock contains from 57 to 60 per cent of tricalcic phosphate, but has also a higher percentage of iron and alumina than the river rock. That portion of the river rock which is low in iron and alumina is mainly shipped abroad.

The excellent quality of the South Carolina product, together with the favorable shipping conditions, place the production on a permanent basis, and the supply of reserve rock known at the beginning of the present decade is calculated to furnish a supply at present rate of consumption for thirty-five years to come. In recent years there has been a slight decrease in the annual production of river rock. The methods of mining and preparation have not changed materially during the past decade except that steam shovels are replacing hand labor for the removal of the overburden and the mining of the land rock. With regard to land rock, Francis Wyatt describes the method of treating it in order to make it marketable as follows: (1) mining or excavating, (2) washing to remove sand and other sterile impurities, and (3) drying in kilns to drive off the contained moisture.

Taking these in their order, it is customary to establish a trunk railroad, starting at the river front or on the bank of some convenient stream, and passing through the center of the property to be exploited. Alternate laterals can be run off at right angles from any portion of this main line, at a distance of say 500 feet, in conformity with the nature of the ground. Between and parallel to these laterals a ditch or drain is dug to a depth extending from 4 to 5 feet below the phosphate strata. From this main drain the excavators start their lines at right angles to the laterals, commencing at one end of the field and digging trenches 15 feet wide and 500 feet long, the work being so arranged that the men are stationed at intervals of 6 feet. Every man is supposed to dig out, daily, a pit 6 feet long, 15 feet wide, and down to the phosphate rock. The overlying material is thrown out to the left-hand side of the trench. The phosphate itself is thrown out to the right and taken in wheelbarrows to the railroad cars which pass at either end of the trench. The water drains from the trenches into the underlying ditch, and is thence pumped out by means of a steam pump worked by a locomotive engine. The pump and the engine are secured to connected railway platforms, and run along the railroad track from one ditch to another as occasion requires.

The cars loaded with the crude phosphatic material dug out of the pits are run down to the washing apparatus, which is constructed at an elevation of 30 feet from the ground, and generally consists of a series of semicircular troughs from 20 to 30 feet long set in an iron framework at an incline of about 20-inch rise in their length. Through every trough passes an octagonal iron-cased shaft provided with blades so arranged and distributed as to form a screw with a twist of 1 foot in 6, which forces the washed material upward and projects the fragments against each other. The phosphate-laden cars are hauled up an incline and their contents dumped into the bottom trough, where the phosphate encounters one or more heavy streams of water, pumped up by a steam pump. This water does not run off at the bottom, but overflows at the higher end near where it enters. When sufficiently washed the material is pushed out upon a half-inch mesh screen, the small débris being received on oscillating wire tables below.

The phosphate is now ready for kilning or drying, and of all the methods hitherto adopted for this important process, that of simple roasting in an ordinary kiln, such as is generally used in the manufacture of bricks, is said to have been found at once the most rapid, effective, and economical. The rock pile is built on layers of pine wood, and owing to its content of a considerable quantity of organic matter it readily lends itself to combustion and requires but a short time to become quite red hot. The kilns are made sufficiently large and are so arranged as to allow free passage to a train of cars, which, running on the main line of railroad, can be loaded in the kiln, run down to the landing place, and discharged directly into the barges or boats on the river.

The total production of phosphate rock in South Carolina, based on marketed output, from 1867 to and including 1902, as reported by the United States Geological Survey, is: Land rock, 6,702,139 long tons; river rock, 3,930,362 long tons; total, 10,632,501 long tons.

Tennessee.—Although the presence of phosphatic nodules in the Chattanooga shale had been known for several years, it was not until 1893 that the industry was started in Tennessee. The deposits are in Hickman and Lewis counties in the central part of the state, but in few places only are they of sufficient quantity and richness to admit of profitable working. The phosphates are classified according to color into blue, brown, and white. The blue rock deposits began to be developed in 1894 in Hickman and Lewis counties over an area of 10 by 20 miles, the principal deposits being adjacent to Swan Creek valley. The great drawback to the exploitation of the blue rock was the distance of the field from the railroad, being 20 miles away; this objection, however, might have been overcome, but the later discovery of the high-grade, easily-moved, brown phosphate rock near Mt. Pleasant, Maury county, 56 miles from Nashville, having direct railroad transportation to the market, reduced the mining of blue rock to inconsiderable proportions. The blue rock occurs in horizontal beds overlying and conforming to the country limestone; the workable beds average 18 inches in thickness and outcrop only where the streams have cut through the overlying strata. In a few cases it can be mined in open cuts by stripping the overburden, but the great bulk of the work must be mined under cover. With an 18-inch seam the mining cost, though high, is offset by the fact that the rock is sufficiently pure to be used without preliminary washing or screening; in fact it is stated to be the only deposit of phosphate yet found in the United States that can be mined and shipped without preliminary treatment. The average composition of the blue rock shows 70 per cent of tricalcic phosphate and from 2.5 to 3 per cent of iron and aluminum oxides. On account of its location away from the railroads the consumption of blue rock is local. With this blue rock occurs a so-called brown rock containing from 74 to 75 per cent of tricalcic phosphate and from 5 to 6 per cent of iron and aluminum oxides.

The general practice of mining is to strip the overburden by hand labor and to quarry the rock in lumps, or to run drifts into the deposit and remove the rock by the ordinary pillar and stall system. Should the material overlying the phosphate rock be such that only a little timbering is required, it will not ordinarily pay to remove the overburden unless it is less than 10 feet in thickness. Ordinarily the stripping of the overbur-

den is a simple matter for the reason that most of the phosphate rock deposits outcrop on a hillside. Generally the rock is crushed to pass through a 2-inch ring and is then treated in a revolving one-quarter-inch mesh screen in order to remove adhering clay and sand; the screened material is ground to from 60 to 80 mesh size and sold for direct use by the farmer or to small superphosphate manufacturers. The rock as it comes from the deposit is comparatively dry and contains on an average more than 60 per cent tricalcic phosphate.

Prior to 1896 the bulk of the production was obtained from the blue rock district where the mines have been developed to a considerable extent. The district was handicapped by long wagon haulage and comparatively costly underground work.

The Mt. Pleasant rock occurs over an area of from 3 to 4 miles north and south and from 6 to 8 miles east and west. There are two varieties—the soft, which constitutes the bulk of the supply, and the hard, which is of minor importance. The soft rock when dry varies in color from grayish or reddish brown to cream white, and occurs in plates of various thickness or size, rarely exceeding 2 or 3 feet in diameter. The plates are closely packed together into a fairly regular stratum which is not uniform in thickness and often sinks into depressions of the underlying limestone. The overburden averages 3 feet in thickness, except in the eastern part of the field where it is too thick in many places to admit of successful mining. The rock is of loose and porous texture and is readily ground when dry.

Two classes of product are made, known locally as domestic and export. The run of mine after the removal of the export lumps, is washed, kiln dried, crushed, and screened, the small particles and dust which pass through forming the domestic product, while the lumps constitute that exported. The export grade is guaranteed 78 per cent of tricalcic phosphate with a maximum of 4 per cent of iron and aluminum oxides; the domestic product is 75 per cent and 5 per cent of these components, respectively.

The hard rock is compact, heavy, oolitic in structure, yellow white in color, and occurs like the blue rock in a well-defined stratum of about two feet in thickness. It is of high grade, but occurs in small quantities. The Mt. Pleasant rock contains no pyrite, but little fluorite and usually a high content of tricalcic phosphate. Washing is necessary in order to remove the iron and aluminum oxides present in the crude rock as it comes from the mines. The mining at Mt. Pleasant is all open-cutwork. From 8 to 9 feet of overburden is removed by hand or with scrapers and the rock removed with pick and bar, no explosive being necessary. Usually the mined rock is dried, under sheds on a cribwork of cord wood, which is fired, yielding a thoroughly dry product. The dry rock is then crushed, screened, and stored or shipped. The high grade material is obtained chiefly from Mt. Pleasant and vicinity, while lower grade deposits exist in Hickman, Giles, and Sumner counties. For the former class of rock there is a good export market, but the low grade rock is consumed mostly at home.

The white rock deposits are in Perry county, the largest development being at Toms creek; it is far from the railroads, but is within 4 miles of the Tennessee river, which affords water transportation. The rock closely resembles Florida land rock in appearance and occurs with chert in pockets of variable size. Selected samples show a high content of tricalcic phosphate and low iron and aluminum oxides. On account of its unfavorable location but little work has been done on this property. White rock is found in other localities in Tennessee, but so far the deposits are of little, if any, importance.

Other states.—The geological survey of Alabama has examined several well-defined deposits, the chief one being the Hamburg bed in Perry county, which is part of a formation extending nearly across the state, although at only one or two points is the material of sufficient richness to make it of importance. The Coatopa bed in Sumter county has been traced for some distance. The Snow Hill bed in Wilcox and Marengo counties carries a higher percentage of tricalcic phosphate than either of the other deposits and holds out more promise of commercial value than any other in the state. There has been no production of phosphate rock in Alabama since 1900, in which year 334 long tons, valued at $534, were produced.

In Arkansas phosphate rock has been found in the counties of Independence, Stone, Izard, Baxter, Marion, Searcy, and Newton, in the northern part of the state, but little prospecting has been done, owing to the distance of the deposits from the railroads. The majority of the samples analyzed prior to 1902 showed a low content of tricalcic phosphate and were high in iron and aluminum oxides. In 1902 a large fertilizer plant was built near Batesville, on the White River Railroad, which was being extended to the mines. Mining operations have been begun in a layer of phosphate rock containing from 50 to 80 per cent of tricalcic phosphate and less than 3 per cent of iron and aluminum oxides. The deposits promise to be of considerable extent and richness, and they will doubtless be developed as soon as the railroad has been completed.

A deposit of phosphate rock has been reported near San Diego, Cal., but the samples sent east showed a small proportion of phosphoric acid and a large content of calcium carbonate.

In Georgia, according to S. W. McAllie, the only commercially important phosphate deposit is near Boston, Thomas county, which was discovered in 1889. The phosphate occurs in nodules of a size ranging from 1 inch to 1 foot in diameter, scattered promiscuously through a reddish sandy clay overlying an irregularly

eroded surface of limestone. In addition to the nodules, which contain from 70 to 78 per cent of tricalcic phosphate, there is also a small proportion of soft phosphate rock. A few carloads of rock were produced in 1889, but the work was abandoned on account of the small quantity of rock available and the great thickness of the overburden.

A small quantity of phosphate rock is mined annually at the shell-rock quarry, Castle Hayne, near Wilmington, N. C. The state owns the mines, and in 1897 proposed to work them with convict labor. In 1898 a land and improvement company was organized to take over the property under contract with the state. During recent years the entire product, which is of very low grade, has been used solely for macadamizing the streets of Wilmington.

The phosphate mines at Ross Farm, Juniata county, Pa., on the Tuscarora Valley Railroad, are operated by a fertilizer company, which erected a large plant for the manufacture of acid phosphate in 1898. The average rock is of low grade, but the good rock, containing more than 50 per cent of tricalcic phosphate, can be easily separated from that of poor grade. The phosphate beds dip steeply into the mountain, and the rock can be delivered at the works, 300 yards distant, at a very low cost.

In Virginia the occurrence of deposits of hard-rock phosphate was reported in Nelson county in 1893 and in Rockbridge county in 1894. An analysis of samples showed that the material was of high grade, but the deposits examined were so inaccessible and small that the rock could not be mined at a profit.

TABLE 6.—DETAILED SUMMARY: 1902.

	United States.	Florida.	South Carolina.	Tennessee.	All other states and territories.[1]

SULPHUR AND PYRITE

SULPHUR AND PYRITE.

By Joseph Struthers, Ph. D.

The statistics for the sulphur and pyrite industries have been united in the present discussion in order not to disclose the operations of 1 company engaged in producing sulphur. Table 1 is a summary of the combined statistics for these 2 industries in 1889 and 1902, and of the statistics of pyrite alone for 1880, no returns for sulphur mining having been made for that year. The expansion of domestic production to meet the increasing demand for sulphur and sulphuric acid is clearly indicated.

Table 1.—*Comparative summary: 1880 to 1902.*

	1902	1889	1880
Number of mines	23	2	1
Number of operators	18	(1)	1
Salaried officials, clerks, etc.:			
Number	54	(2)	(1)
Salaries	$49,890	$5,512	(1)
Wage-earners:			
Average number	970	249	6
Wages	$398,870	$64,789	$1,200
Contract work	$3,587	$23,103	(1)
Miscellaneous expenses	$39,118	$30,262	(1)
Cost of supplies and materials	$217,262	$43,700	$365
Product:[3]			
Quantity, long tons	207,874	106,100	2,240
Value	$947,089	$209,969	$5,000

[1] Not reported.
[2] Not reported separately.
[3] Includes in 1902, 11,483 tons of pyrite, valued at $29,420, produced as a by-product of coal mining.

For the twenty-two years covered, the table shows an increase in production of over one-hundredfold, and in value of nearly one hundred and ninety fold. When the total amount of sulphur consumed (as sulphur, not including pyrite) is taken into consideration, the amount of the domestic production in 1902 was not relatively large, but the steady increase indicates the substantial nature of the industry. In 1880 the industry was small—only 1 pyrite mine with a product valued at $5,000 being reported, but in 1889 the value of the production of sulphur and pyrite was $209,969. This increased to $947,089 in 1902. The growth from 1880 to 1889 was greater proportionately, but that from 1889 to 1902 was larger in absolute amount.

Three sulphur mines were reported idle in 1902—1 in Colorado and 2 in Utah; and 5 pyrite mines—1 each in Alabama and Ohio, and 3 in Virginia. At 1 sulphur mine in Texas development work was reported.

Capital stock of incorporated companies.—Of the 18 operators in the United States in 1902, 14 were organized as incorporated companies. The details of their capitalization are shown in Table 2.

Table 2.—*Capitalization of incorporated companies: 1902.*

	United States.	Virginia.	All other states.
Number of incorporated companies	14	2	[1] 12
Number reporting capitalization	12	2	[2] 10
Capital stock:			
Total authorized—			
Number of shares	46,000	12,500	33,500
Par value	$4,260,000	$1,250,000	$3,010,000
Total issued—			
Number of shares	38,850	7,500	31,350
Par value	$3,545,000	$750,000	$2,795,000
Dividends paid	$2,400		$2,400
Common—			
Authorized—			
Number of shares	42,500	12,500	30,000
Par value	$3,910,000	$1,250,000	$2,660,000
Issued—			
Number of shares	37,500	7,500	30,000
Par value	$3,410,000	$750,000	$2,660,000
Dividends paid	$2,400		$2,400
Preferred—			
Authorized—			
Number of shares	3,500		3,500
Par value	$350,000		$350,000
Issued—			
Number of shares	1,350		1,350
Par value	$135,000		$135,000

[1] Includes companies distributed as follows: Alabama, 1; California, 2; Louisiana, 1; Massachusetts, 1; Missouri, 1; Nevada, 1; New York, 1; Ohio, 3; Washington, 1.
[2] Includes companies distributed as follows: Alabama, 1; Louisiana, 1; Massachusetts, 1; Missouri, 1; Nevada, 1; New York, 1; Ohio, 3; Washington, 1.

These companies reported a total capital stock issued of a par value of $3,545,000. This was made up of 37,500 shares of common stock, 88 per cent of the number authorized, having a par value of $3,410,000, which is 87 per cent of the total par value of the $3,910,000 authorized; and 1,350 shares of preferred stock having a par value of $135,000, these amounts being each 90 per cent of the number of shares and total value of the preferred capital stock authorized. There was no bonded indebtedness.

Employees and wages.—The average number of wage-earners employed each month during 1902 is shown in Table 6. The employment was comparatively steady. The average number of wage-earners for the entire year was 970. The highest monthly average, 1,059, reported in July, exceeds this by only 89, and the lowest, reported in December, falls short of it by 151, a total variation of 240, or 24.8 per cent of the yearly average. Child labor constituted only 13.4 per cent of the whole.

Table 6 shows also the average number of wage-earners employed at specified daily rates of pay during 1902.

The rate group comprising the greatest number of wage-earners is that from $1 to $1.24 per diem, 30 per cent of the entire number being included within these rates. Of the employees, 205, or 21.1 per cent, received from $1.25 to $1.49 per day; 662, or 68.2 per cent got between $1 and $1.74 per day; 146, or 15 per cent of the total, were employed at a rate of $2 or more, and 117, or 12.1 per cent, received less than $1 per diem. Of the 970 wage-earners, 429, or 44.2 per cent, were employed below ground. Miners and quarrymen numbered 301, or 31 per cent, and 110, or 36.5 per cent of these, received from $1.25 to $1.49 per day, the remainder being distributed mostly among the higher rate groups, 6 receiving from $3 to $3.24. "All other wage-earners" numbered 405, or 41.8 per cent, their greatest concentration, 48.1 per cent, being in the rate group from $1 to $1.24.

Mechanical power.—The primary power reported for the sulphur and pyrite industry aggregated 6,305 horsepower. Of this 5,915 horsepower was generated by steam, 20 by gas or gasoline, 50 by rented waterpower, and 320 by air compressors. Two electric motors, having a capacity of 80 horsepower, were also reported.

Production.—In the following table the figures for the domestic production and the imports of sulphur and pyrite are given, so far as obtainable, for the years 1880 to 1902. The statistics for the two minerals are presented separately except for 1902, a combination for that year being necessary to avoid disclosing the operations of a company engaged in producing sulphur. The quantity of sulphur displaced by the use of pyrite is also shown.

TABLE 3.—ANNUAL DOMESTIC PRODUCTION, IMPORTS, AND TOTAL CONSUMPTION OF SULPHUR AND OF PYRITE, WITH PERCENTAGE DOMESTIC PRODUCTION IS OF TOTAL CONSUMPTION, AND QUANTITY OF SULPHUR DISPLACED BY PYRITE: 1880 TO 1902.

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

YEAR.	SULPHUR.						PYRITE.						Quantity of sulphur displaced by use of pyrite (long tons).[2]
	Total consumption (long tons).	Domestic production.			Imports.		Total consumption (long tons).	Domestic production.			Imports.[1]

[1] Previous to 1884 classed among sulphur ores; 1887 to 1891 classed among other iron ores; since 1891 includes iron pyrite containing 25 per cent or more of sulphur.

[2] Estimated on basis of 45 per cent sulphur content.

[3] The statistics of the domestic production and total consumption of sulphur are combined with those of pyrite to avoid disclosing the operations of a company producing sulphur.

The quantity of sulphur produced each year in this country has been a relatively small part of the total consumption of the commodity. In no year during the period covered by the table has this proportion exceeded 3.8 per cent, but a comparison of the fluctuation makes it evident that this proportion tends to increase. The imports have increased from 88,119 long tons in 1880 to 174,939 long tons in 1902.

Practically all the pyrite consumed in 1882 was of domestic production, but in 1901 this source yielded only 36.8 per cent of the total. Owing to trade conditions the foreign pyrite can be more profitably utilized than can the domestic ore. Hence the imports have constantly grown until they now form almost two-thirds of the total consumption.

The recovery of the sulphur content of pyrite has steadily encroached upon the field formerly occupied almost exclusively by sulphur. Estimated on an average sulphur content of 45 per cent, the quantity of sulphur displaced by the use of pyrite has grown from

93,233 long tons in 1891 to 287,339 long tons in 1901. This latter figure exceeds the domestic production of sulphur by 280,473 long tons.

Imports of sulphur.—Table 4 shows the importation of sulphur into the United States for 1900, 1901, and 1902, the exporting countries, and the customs district at which the sulphur was entered.

Relative production of sulphur by various countries.—In order to show the production of sulphur by the different countries of the world, the following table has been compiled from data gathered by the United States Geological Survey. This table indicates that nearly 90 per cent of the world's production of sulphur is obtained from Italy.

[1] Crude rock. [2] Statistics not yet reported.

A detailed summary of the industry is given in Table 6.

DESCRIPTIVE.

SULPHUR.

Sulphur has been known to mankind from the earliest records of history. It is one of the most important elements that comprise the earth's crust, and occurs in a free or uncombined state in many countries, forming the mineral sulphur, more commonly known in commerce as brimstone.

Physical and chemical characteristics.—The element is insoluble in water and nearly so in alcohol and ether, but is quite soluble in carbon disulphide, petroleum, and benzine. It burns in air with a blue flame, and is oxidized into sulphur dioxide or sulphurous acid. It exists in two distinct crystalline forms, and also as an amorphous variety. These modifications are characterized by differences in specific gravity, in solubility in various liquors, and in many other respects.

Sulphur is a pale-yellow, brittle, crystalline solid, with a resinous luster, is almost tasteless, and emits a peculiar characteristic odor when rubbed or warmed. It is a nonconductor of electricity and an extremely bad conductor of heat. When very gently warmed, even by being grasped in the hand, it may be heard to crack by the mere warmth, and will ultimately fall to pieces. At a temperature of 114.5° C. it melts into a clear amber-colored and moderately mobile liquid; on raising the temperature of this liquid, its color rapidly darkens, and at the same time it loses its mobility until

at a temperature of about 230° C. the mass appears almost black, and is so viscous that it can no longer be poured from the vessel. As the temperature is still further raised the substance, while retaining its dark color, again becomes liquid, although it does not regain its former limpidity. At 448° C. the liquor boils and is converted into a pale yellowish-brown colored vapor. In cooling the same changes occur in reverse order. The atomic weight is 32. The specific gravity of ordinary octahedral sulphur is 2.05; of prismatic sulphur, 1.96.

Uses.—Sulphur is used in the preparation of sulphuric acid, in the manufacture of gunpowder, in making friction matches, in vulcanizing rubber, as an insecticide, and in medicine as a laxative, and for certain skin diseases.

Minerals of sulphur.—Sulphur occurs in combination with other elements, forming the large and important groups of minerals, the sulphides and the sulphates. Of the sulphide minerals, the combinations with the metallic elements are of primary industrial importance, and, with the possible exception of the iron sulphides, they form the ores from which many of the base metals are obtained.

The principal sulphide and sulphate combinations are as shown below.

Sulphide and sulphate combinations.

COMBINATION OF ELEMENTS.	Name of mineral.	Chemical formula.
Chief sulphide minerals:		
Sulphur and iron	Pyrite	FeS_2
Sulphur and iron	Marcasite	FeS_2
Sulphur and iron	Pyrrhotite	$Fe_{11}S_{12}$
Sulphur and copper	Chalcocite	Cu_2S
Sulphur and copper and iron	Chalcopyrite	$CuFeS_2$
Sulphur and copper and iron	Bornite	Cu_3FeS_3
Sulphur and lead	Galenite (galena)	PbS
Sulphur and zinc	Sphalerite (zinc blende)	ZnS
Sulphur and silver	Argentite	Ag_2S
Less important sulphide minerals:		
Sulphur and arsenic	Realgar	AsS
Sulphur and arsenic	Orpiment	As_2S_3
Sulphur and antimony	Stibnite	Sb_2S_3
Sulphur and molybdenum	Molybdenite	MoS_2
Sulphur and mercury	Cinnabar	HgS
Sulphur and nickel	Millerite	NiS
Sulphur and tin	Tin pyrites	SnS_2
Chief sulphate minerals:		
Sulphur and calcium	Gypsum	$CaSO_42H_2O$
Sulphur and calcium	Anhydrite	$CaSO_4$
Sulphur and barium	Barite	$BaSO_4$
Sulphur and magnesium	Epsomite (Epsom salt)	$MgSO_47H_2O$
Sulphur and strontium	Celestite	$SrSO_4$
Sulphur and sodium	Thenardite (Glauber salt).	Na_2SO_4
Sulphur and lead	Anglesite	$PbSO_4$
Important artificial sulphates:		
Sulphur and copper	Copper sulphate (blue vitriol).	$CuSO_47H_2O$
Sulphur and iron	Iron sulphate (copperas).	$FeSO_47H_2O$
Sulphur and zinc	Zinc sulphate (white vitriol).	$ZnSO_47H_2O$

Sulphur dioxide (SO_2) is the direct combination of sulphur with oxygen and is found naturally as a minor constituent of the atmosphere, particularly near volcanoes, and over large cities, where its presence is due to the oxidation of the sulphur contained in the fuel burned.

In vegetables sulphur exists in some of the tissues of plants, although not in the woody tissues. In animals it constitutes an essential element of the blood, muscles, skin, hair, and other parts.

Hydrogen sulphide (H_2S) and sulphur dioxide (SO_2) are evolved from volcanoes as gases, which are doubtless the products of the action of the water of the ocean which has penetrated to the interior of the volcano upon the molten metallic sulphides that exist there.

The two forms in which the sulphur is marketed are the flour, or flowers, of sulphur, which is a light powdery form of the substance caused by the condensation of sulphur vapor; and brimstone, or sulphur, which is made usually by melting this soft powder and molding the liquid thus obtained into large blocks or cylindrical rods in wooden molds.

Occurrence.—Natural deposits of sulphur are sometimes found stratified with beds of clay or rock, but they often occur as what are known as "living" beds, in which the sulphur is continuously being formed as the result of active chemical decompositions. In such a living sulphur bed the sulphur is produced by the direct action of sulphurous gases, especially hydrogen sulphide (H_2S) and sulphur dioxide (SO_2), which in the presence of moisture (H_2O) react and form water (H_2O) and sulphur (S). These gases emanate in regions of active or expiring volcanoes, and form the so-called solfataras, in which the sulphur has been condensed from the vapors formed and has collected in cracks in the lava and tuffs or in the kaolin or clay formed by the corroding action of the acid vapors on the lavas.

From a commercial standpoint, especially for the manufacture of sulphuric acid, the mineral from the solfatara deposits is not regarded favorably on account of its liability to contain arsenic in the form of the minerals orpiment (As_2S_3) and realgar (AsS). Sulphur of this character has been imported from the island of Vulcano, one of the Lipari group, off the coast of Italy. A similar association of arsenic minerals has been reported in the sulphur deposits in Yellowstone National Park. Traces of selenium and tellurium, which are also objectionable in the manufacture of sulphuric acid, occur in the volcanic sulphur deposits in Japan. The only solfatara deposits of commercial importance at the present time are in southern Utah and in the island of Hokkaido, Japan.

The world's supply of sulphur is derived from two principal sources: (1) The deposits of the native mineral sulphur, which yield the sulphur or brimstone of commerce; and (2) the deposits of the sulphide minerals—pyrite, pyrrhotite, chalcopyrite, sphalerite, and other sulphides—from which is derived the sulphur dioxide gas used in the manufacture of sulphuric acid. In addition to these two natural sources of sulphur, there are several artificial products containing sulphur, chiefly in the form of sulphur dioxide gas, in sufficient quantity to admit of commercial utilization. There are also lead, copper, and other mattes from the furnace

treatment of various lead and copper ores and alkali waste from chemical works engaged in manufacturing soda.

During recent years, however, several thousand tons of sulphur have been produced annually in England from the accumulated alkali waste of the Le Blanc soda process. This manufactured product is known as "chance-claus," or recovered sulphur. The process of its manufacture reproduces, in many respects, the chemical reactions by which natural sulphur is formed from gypsum.

REVIEW OF THE INDUSTRY IN THE UNITED STATES.

The development of the sulphur mining industry in the United States has been of very slow growth, owing principally to the cheapness with which the refined product can be imported from Italy. In recent years nearly the entire supply has been obtained from the enormous deposits in the island of Sicily, which supplies, as well, by far the greater part of the rest of the world's demand. The deposits of sulphur which have been worked in the United States are limited in number. The states from which, during 1902, the domestic supply of native sulphur was derived are, in the order of the quantity of their output, Louisiana, Nevada, and Utah.

The following is a brief summarization of the progress that has been made in extracting and refining the sulphur of the deposits in this country.

Louisiana.—An immense deposit of sulphur of the gypsum type occurs in Calcasieu parish, 230 miles west of New Orleans and 12 miles from Lake Charles. This is unquestionably the most accessible of the American deposits, and, in all probability, it is the richest as well. Exceptional difficulties have been encountered in developing the mine, owing to quicksand and gravel which overlie the mineral. As proved by a number of drill holes, the bed of sulphur is from 110 to 125 feet in thickness, the upper level being about 350 feet below the surface.

In the working of the Frasch process,[1] a well is sunk by a drill precisely in the same way as for petroleum.[2] This well is cased with an iron pipe 10 inches in diameter, which enters the rock overlying the bed of sulphur for a distance of 10 feet, the joint being subsequently sealed as well as possible by molten sulphur in order to exclude water. Inside the 10-inch pipe is placed one of 6-inch diameter; inside the latter, one of 3-inch diameter; and, finally, inside the 3-inch pipe, one of 1-inch diameter. The well itself is carried down to the bottom of the sulphur bed, and the 6-inch and smaller pipes are extended nearly to the bottom of the well. The inner pipes are recovered when the well is abandoned. The method of extracting the sulphur is as follows: Steam at a temperature of 330° F. is forced down the 10-inch and 6-inch pipes under a corresponding pressure. When the steam comes in contact with the sulphur (which at 284° F. becomes liquid), the latter melts and collects in the well as a thin liquid of a specific gravity of about 2. At first the molten sulphur was pumped out through the 3-inch pipe in a manner similar to that followed in pumping petroleum from a well, the working valve being formerly of aluminum, which is not affected by sulphur. It was found, however, that the aluminum was not strong enough to withstand the shock of the heavy column at the change of stroke, and the method had to be abandoned. Later, the 1-inch pipe referred to above was introduced into the 3-inch pipe, and through it compressed air was forced. The bubbles of air mixed with the sulphur reduce the specific gravity of the column of sulphur and cause it to rise with rapidity. This latter method of extraction has not been entirely satisfactory, and it may have been modified or replaced by some other more efficient method. The sulphur produced is practically refined sulphur, and finds a ready sale on account of its purity and attractive appearance.

It is not practicable to ascertain precisely what occurs at the bottom of the well, but it may be assumed that as the sulphur melts out of the bed it forms a more or less pear-shaped cavity, which becomes larger and larger, until finally the increased surface exposed to the water is sufficiently great to reduce the temperature of the water below the melting point of the sulphur, while the impurities of the bed collect on the bottom and the sides of the chamber and protect the sulphur still unfused from the melting action of the heated water. If the bed of sulphur is very pure the chamber might become quite large in size, when the unsupported overlying roof would fall and allow the water to escape through the overlying beds.

Although the Frasch process is very ingenious and the inventor deserves great credit for working out the numerous details, yet its application to the deposits of sulphur has greatly injured them, since the exploitation of the deposit by shafts and the common method of underground mining has now become fraught with danger, owing to the uncertain extent of the openings from which the sulphur has been dissolved by the Frasch experiments. In view of the heavy flow of water which may be expected through certain of the strata this uncertainty is an element of great peril.

Nevada.—Sulphur occurs at Rabbit Hole Springs, 35 miles from Humboldt House, in Humboldt county. The deposit is of the solfatara type; and the sulphur, associated with gypsum, etc., fills the craters of a few extinct hot springs. The sulphur rock is in beds of considerable thickness and extent, included between limestone and magnesian rocks. The ore occurs in masses of various sizes up to several hundred pounds in weight, which are mixed with clay among heaps and

[1] United States patents, Nos. 461429, 461430, and 461431 of October 20, 1891.

[2] The Mineral Industry, Vol. V, pages 514 and 515.

layers of ashes and light gravel. The ore is mined by adits and drifts run in from the level of the wagon road, which extends entirely around the hill at a considerable elevation. All rock containing more than 8 per cent of sulphur is mined, and the product is taken to the refinery and refined in iron kettles heated by dry steam. The refined product is carried in wagons to Humboldt House and shipped thence by rail, chiefly to the powder factories and acid makers on the Pacific coast.

Utah.—The deposits which are the source of most of the sulphur mined in Utah are located in Beaver county near the Millard county line. They were known to the early pioneers, who obtained small quantities of almost pure sulphur from the numerous caves in that vicinity. Soon after the year 1870 the claims were located under the mining laws, and a small refining furnace was installed which was worked intermittently until the year 1891, when the property changed owners, and the plant was modernized and enlarged. Under the new management, the mining operations of the company have been continuous and successful. The ore is removed by open cutting, and the furnaces are worked during the summer only. Four of the six stacks in the refining plant are generally operated at a time, and about 50 tons of 20 per cent rock are treated daily, yielding the refined product in the form of roll sulphur, which is sold as such or is ground in mills to make flour sulphur.

Deposits in other states and in Alaska are thus described:

Alaska.—There are a number of sulphur deposits of the solfatara type on the volcanic islands off the coast of Alaska. The largest so far as known is on the island of Kadiak, but others are recorded on Unalaska and Akutan islands, and on an unnamed island southeast of Akun Island. The deposits have not yet been exploited beyond the prospecting stage.

California.—At Sulphur Bank, on Clear Lake, 40 miles north of San Francisco, a deposit of sulphur occurs in the white siliceous residue of a basalt flow that has been decomposed by the uprising solfatara and the sulphur deposited. Some 25 years ago this deposit contributed a small quantity to the domestic supply of the United States, but as the development work went deeper cinnabar was found, and sulphur was no longer produced. A deposit of sulphur was worked for a time in Colusa county, and a small refinery was erected, but during the past decade little, if any, sulphur has been produced in this county. The occurrence of sulphur has also been reported in other localities in California, but nowhere in sufficient quantity to warrant its extraction as a commercial product.

Idaho.—The occurrence of sulphur has been reported near Swan Lake, Custer county, and also near Soda Springs, in Bannock county. The deposits have not yet been developed to any great extent, although there was a small output in 1901.

Texas.—The sulphur deposits in the northeastern part of El Paso county have been known since 1854, when they were noticed by Prof. William P. Blake, who was then the geologist of an expedition for the survey of a railroad route from the Mississippi river to the Pacific ocean, which was made by the United States War Department. The region in which the deposits occur is from 13 to 60 miles from the railroad. The nearest railroad station, Guadalupe, on the Pecos Valley Railroad, is 42 miles north of Pecos. The sulphur occurs in the form of small crystals embedded in white gypsum, and in some instances the ore contains as much as 25 per cent of native sulphur. The area of the region thus far prospected is small, but there are other localities of promise awaiting examination.

Method of refining sulphur.—It has been proposed to separate sulphur from the ore by heating it with hot air, with steam under pressure, or with superheated steam. But these methods have been unprofitable on account of the cost of fuel in those regions where sulphur occurs. Sulphur may be extracted from the ore by a solvent, such as carbon disulphide, which may be recovered afterwards, but this method necessitates an expensive plant. For some ores a treatment with a solution boiling above the melting point of sulphur has proved successful. The ore is placed in an iron basket or crate in a boiling solution of calcium chloride,[1] which boils at 125° C. The sulphur melts and flows away from the matrix of stones, etc.; passing through the meshes of the basket and falling to the bottom of the tank, it is drawn off and cast in molds. After it is melted out, the basket of hot stones is lowered into a tank of water, which is heated by the stones, while it removes the adhering calcium chloride from them. This warm water is then used to replace that lost from the boiling calcium chloride solution. This process causes no loss of sulphur as sulphur dioxide, and no nuisance is created, while a fairly pure product is obtained. The calcium chloride used is a waste product of the ammonia soda industry.

In the United States, the extraction of sulphur by means of superheated steam[2] has been tried, and an excellent quality of sulphur has been obtained without formation of any sulphur dioxide. The cost of fuel in the West, however, is an obstacle to the further development of this method. In Louisiana, as mentioned earlier in this paper, steam is forced, under pressure, through driven wells or tubes, into the sulphur deposit, which partly refines the sulphur, liquefied by the heat. The molten product is forced to the surface by the

[1] Vincent: Bull. Soc. Chim., 40, 528. Am. Chem. Jour., VI, 63.
[2] J. Soc. Chem. Ind., 1887, 439, 442; 1889, 696.

steam pressure through a small pipe inside of the steam pipe.

Generally the method of extracting the sulphur from the ore, and at the same time of partially refining it, is to treat the ore in a cylindrical or slightly conical cast-iron vessel of a capacity of about 5 tons of ore. Steam inlets are provided at the top and bottom; also a bottom valve through which the melted sulphur is withdrawn and cast into molds. The size and the form of this refining vessel depends to some extent upon the nature of the material to be treated. If the ore is porous, a higher vessel of greater capacity can be used, and with ores that increase their volume considerably from the action of the heat, the bottom of the vessel should be made of much larger cross section than the top, in order to facilitate the discharge of the spent ore after the sulphur has been extracted. The steam jets are so arranged that the melted sulphur can not accumulate at any point within the vessel except at the bottom. If properly arranged and operated the extraction of sulphur by means of superheated steam should be accomplished with the loss of not more than from 1.5 to 2 per cent of the quantity of sulphur treated.

Sulphur deposits of Italy.—Owing to the importance of the sulphur deposits of Italy, the following brief outline of the methods of mining and refining adopted in that country will be found of interest.[1]

In Sicily the sulphur mineral is disseminated through the matrix, sometimes in considerable masses of nearly pure sulphur, but usually in fine seams or grains. The methods of obtaining it are very crude and wasteful. The mines are for the most part open pits, ranging from 200 to 500 feet in depth, and the ore is carried to the surface in baskets or sacks by laborers, who ascend by inclined paths on the walls of the pit. In a few of the better mines, however, hoisting machinery is now used, but the introduction of this method has met with the determined opposition of the laborers.

The ore is generally refined in a very simple manner, the process being carried on in kilns called "calceroni." As usually constructed, these are shallow pits about 30 feet in diameter, with walls about 10 feet high, made tight with mortar. They are generally built on a hillside, and the sloping bottom is beaten smooth. The ore is arranged in the calcerone so as to leave a few vertical draft holes from top to bottom of the heap, which is fired by dropping burning brush or straw into these openings. The sulphur, which forms from 25 to 40 per cent of the ore, burns freely, and when the heap is well on fire the draft holes are closed, the calcerone covered with spent ore, and the whole left for several days. The heat given out by the burning of part of the sulphur is sufficient to melt the remainder from the gangue, and it collects in a pool near a tap hole made in the wall at the lowest point. At intervals of a few hours the melted sulphur is drawn off into molds. If the temperature rises above 180° C. (356° F.), there is a large formation of plastic sulphur, which will not flow from the tap hole. The time necessary to burn out a calcerone varies from thirty-five to eighty days, according to its size, the weather, and the nature of the impurities; for example, much gypsum retards the process, owing to the water it contains. Usually from a quarter to a third of the sulphur is lost as sulphur dioxide during the burning. As this causes much damage to vegetation in the vicinity, the burning of calceroni is prohibited during the spring and summer months.

[1] F. H. Thorp: Outlines of Industrial Chemistry, 1898.

PYRITE.

The name pyrite is derived from the Greek word *πυρίτης* meaning "of the nature of fire," and alludes to the property possessed by the mineral of producing sparks when struck with a hard substance. Specifically, the name pyrite is restricted to the isometric crystalline form of the native iron bisulphide mineral (FeS_2) containing 46.6 per cent of iron and 53.4 per cent of sulphur. The mineral marcasite is also a native iron bisulphide (FeS_2) of identically the same chemical composition as pyrite, but it occurs in crystals of the orthorhombic system of crystallization. In a general sense, pyrite includes that class of native minerals in the massive or crystalline form composed of a metallic sulphide or arsenide, or both. Iron, copper, nickel, and cobalt pyrites are the principal minerals of this class.

Occurrence.—Pyrite occurs abundantly in rocks of all geologic ages, from the oldest crystalline to the most recent alluvial deposits. In crystalline formation it usually occurs in small cubes, pyritohedrons, or in more highly modified shapes; also in irregular spheroidal nodules, and in the massive form in clay slate, argillaceous sandstone, coal formation, etc.

Uses.—Pyrite is used principally in the manufacture of sulphuric acid. Recently it has also been used in pyritic and allied smelting processes and, to some extent, in making sulphur dioxide gas for use in bleaching wood pulp. In vulcanizing rubber and in the preparation of medicinal compounds the use of pyrite is impracticable.

Deposits and mining in the United States.—The deposits of pyrite in the United States are quite numerous and widespread. The largest deposits so far discovered are at Mineral, Va., and Charlemont, Mass. Deposits are also found in Alabama, California, Georgia, Indiana, New York, and Ohio. The mineral was mined in these states in 1902. Virginia supplied nearly one-half of the total. The production in Indiana and Ohio was in the form known as "coal brasses," ob-

tained as a by-product in the mining of coal. The total quantity so produced, however, was but a small proportion of the total output of the United States. It is not probable that the production of pyrite from this source will ever become of importance.

There are many other deposits of pyrite in the United States, but they have not been exploited because of the impure or low-grade quality of the ore and the excessive cost of mining and of transportation both to and on the railroads leading to the centers of consumption. Some of the ores not now deemed of sufficient value to be worked for their sulphur content will eventually be profitably treated by modern methods. In the Southern states particularly are many deposits of this character, which could produce enormous amounts of sulphuric acid in this manner at prices lower than the present average prices at the seaboard. A condition which has served to retard the growth of the production of the domestic ore lies in the fact that foreign ores can be imported and accumulated at the seaboard and shipped inland in quantities sufficiently large to secure very low freight rates.

A promising prospect for the pyrrhotite ores of the South lies in the feasibility of their utilization for the manufacture of sulphuric acid. It is claimed that the sulphur contained in these ores can be so effectually removed that the residual product will be of value in the manufacture of pig iron or even of steel. For this purpose the cinders or residues from the roasting of pyrite for the manufacture of sulphuric acid have been utilized to advantage. It is well known that the residues from Spanish ores treated by the Henderson process have been sold either in the form of "fines" or "briquetting" and utilized in the manufacture of steel, but in the United States roasted pyrite residues have not yet been utilized for the manufacture of iron on account of the large percentage of sulphur remaining in them after treatment in the chemical works. If pyrite residues could be roasted so that the amount of sulphur remaining after treatment would be so small as to permit of their utilization for the manufacture of pig iron, there would result an annual saving of many thousand tons from what is now a waste product. As yet, however, the recovery of sulphur and iron from these ores is in an experimental state.

Other experiments have recently been conducted for the utilization of the by-product gases resulting from the roasting of zinc blende ores, the practicability of which has been demonstrated with financial profit at the zinc plants of Peru and Lasalle, in Illinois, and of Argentine, in Kansas. It is feasible to save from 25 to 28 per cent of the sulphur content of the zinc ores during the roasting, which yields a product containing not more than 2 per cent of sulphur. By subsequently roasting this product—cinders, as it is called—in the Chase or other type of special roasting furnace the remainder of the sulphur will be expelled, and the dead-roasted zinc ore will then be in proper condition to permit of the extraction of the zinc at very low cost. There is an immense supply of sulphur in the zinciferous sulphide ores of Arkansas, Colorado, Kansas, Kentucky, Missouri, and other states, and it is well within the range of probability that ere long the tonnage of sulphur derived from pyritiferous ores will be largely augmented by the utilization of the sulphur contained in these zinc sulphide ores.

An important factor in the development of the pyrite industry is the demand for sulphuric acid in the treatment of phosphate rock, and in the refining of petroleum. Since a chemically pure sulphuric acid is not essential for these purposes, the acid made from pyrites serves quite as well as that made from sulphur. Another field for the future extension of the utilization of the pyritiferous ores lies in the making of sulphur dioxide gas for use in bleaching wood pulp, which is the basis of the manufacture of paper by the sulphite process. Heretofore American manufacturers of paper using this process, with one or two exceptions, have been limited to the use of sulphur for making sulphur-dioxide gas, although in Europe a considerable quantity of pyrite has been thus utilized. It is quite probable that the difficulties that have heretofore existed in the way of utilizing pyrite in the bleaching of pulp will be overcome in the near future. When this becomes an accomplished fact it will open up a large field for the consumption of pyrite in New York state, and also of the lean cupriferous pyritic ores of the New England states. Where the conditions are favorable for deep mining and concentration and for shipment to the numerous paper mills of that section, constant and large supplies of sulphur will thus be guaranteed at prices much lower than can be expected from outside sources.

THE MANUFACTURE OF SULPHURIC ACID.

The manufacture of sulphuric acid is of great industrial importance, as the acid is of primary importance in the manufacture of phosphate rock fertilizers and in the refining of petroleum. It is also required in the manufacture of other acids and chemical salts, and has a very wide field in the making of alizarin dyes, artificial indigo, and many other important chemical salts. Of the immense quantities of sulphuric acid made yearly, the greater part does not appear on the market; because of the expense and difficulty of shipping it, consumers of large amounts generally make their own acid.

Until a few years ago the total quantity of ordinary sulphuric acid produced in the world had been obtained by burning crude sulphur in air, the resultant sulphur dioxide gas being then passed, together with

steam and an oxidizing agent, generally nitric oxide, into lead-lined chambers, where these gases react on one another and form the dilute acid, which is subsequently purified and concentrated to the desired degree of strength. This process is called the lead-chamber process, but a newer and more satisfactory process is the "contact" process, in which the sulphur dioxide gas, in the presence of so-called "catalytic" substances (platinum sponge, platinized asbestos, iron oxide, etc.) is directly oxidized to sulphur trioxide (SO_3), which is then absorbed in water to form sulphuric acid of any degree of strength. Recently it has been found more economical in making sulphuric acid to utilize the sulphide minerals as the source of sulphur dioxide gas. In this manner the more costly brimstone is reserved for purposes other than acid manufacture, and for which the sulphide minerals would not be applicable.

The use of pyrite as a raw material in the manufacture of sulphuric acid was first proposed by an Englishman named Hill, who obtained a patent for the process in 1818. It was not until 1838, however, when the price of crude sulphur was nearly trebled by the French firm who had purchased from the Sicilian government the monopoly of the sulphur exportation from that island, that the use of pyrite by acid makers attained any importance. In the United States, which leads the world in the consumption of sulphur, this substitution of pyrite for sulphur in acid making has continued steadily during the past twenty-five years, and owing to its cheapness and widespread occurrence, pyrite has almost completely replaced the crude sulphur that was formerly used almost exclusively. This change in acid making has resulted largely from the treatment of phosphate rock by sulphuric acid, by which it is made into valuable fertilizer, and also from the use of the acid in the refining of crude petroleum. For these purposes the use of a high-grade, pure sulphuric acid is not essential. Unrefined sulphuric acid made from pyrite is generally contaminated with arsenic, and frequently with the additional impurities, copper, zinc, and selenium, but not in sufficient quantities to bar its use in preparing fertilizers or in refining the crude petroleum. The impurities, too, may be removed if desired, and a pure acid produced.

To give some idea of the large quantities of the acid consumed in these industries, it may be stated that 1 pound of acid of chamber strength is required to convert each pound of crude phosphate rock into acid phosphate or commercial fertilizer, and during 1902 over 1,500,000 long tons of the crude phosphate rock were mined. In refining crude petroleum each gallon of commercial petroleum (kerosene) requires 1 pound of sulphuric acid of a strength of 66° B. for its production, and during 1902 the output of crude petroleum in the United States amounted to over 89,000,000 barrels, each of 42 gallons capacity. In estimating the quantity of acid consumed in these two industries alone, any calculation based upon figures of production, less imports, both of crude petroleum and phosphate rock, must necessarily be tentative and not even closely approximate, for the reason that it is impracticable to ascertain the exact quantities of stock of crude material on hand at the beginning and at the close of a year. For practical purposes, however, it may be assumed that the consumption of sulphuric acid in the United States at the present time is approximately in the following proportions: For the treatment of phosphate rock, 50 per cent; for refining crude petroleum, 38 per cent; and for use in the chemical trade, 12 per cent.

In making sulphuric acid from pyrite, pieces of the mineral ranging in size from several inches in circumference to extreme fineness are burned with access of air in a furnace, of which there are many forms, each suited for some special physical or chemical characteristic of the ore. As a result of the burning, or oxidation, the sulphur content of the pyrite or pyritiferous ore is converted into sulphur dioxide gas. When the ore contains over 30 per cent of sulphur, the heat generated by the oxidation of the sulphur is sufficient to maintain combustion without fuel. The sulphur dioxide gas produced in this manner is purified, and subsequently converted into sulphuric acid, either by the chamber process, in which the oxidation is accomplished by nitric oxide gases and steam, or by the contact process, previously described.

TABLE 6.—DETAILED SUMMARY: 1902.

	United States.	Virginia.	All other states.[1]
Number of mines	23	6	17
Number of operators	18	4	14
Character of ownership:			
Individual	1	1	.....
Firm	3	1	2
Incorporated company	14	2	12
Salaried officials, clerks, etc.:			
Total number	54	32	22
Total salaries	$49,890	$29,970	$19,920
General officers—			
Number	6	4	2
Salaries	$9,050	$7,450	$1,600
Superintendents, managers, foremen, surveyors, etc.—			
Number	31	17	14
Salaries	$28,582	$13,952	$14,630
Foremen below ground—			
Number	7	3	4
Salaries	$5,390	$3,200	$2,190
Clerks—			
Number	10	8	2
Salaries	$6,868	$5,368	$1,500
Wage-earners:			
Aggregate average number	970	655	315
Aggregate wages	$398,870	$222,986	$175,884
Above ground—			
Total average number	541	389	152
Total wages	$199,315	$122,431	$76,884
Engineers, firemen, and other mechanics—			
Average number	126	105	21
Wages	$57,957	$45,037	$12,920
Miners—

[1] Includes operators distributed as follows: Alabama, 1; California, 2; Georgia, 1; Louisiana, 1; Massachusetts, 1; Missouri, 2; Nevada, 1; New York, 1; Ohio, 3 (6 mines); Utah, 1.

[2] Includes timbermen and track layers.

BARYTES

BARYTES.

By Joseph Hyde Pratt.

The mining of barytes has been carried on in the United States for about fifty years, but it is still an industry of minor importance. Barytes was first produced in small quantities for use as an adulterant of white lead. Statistics of production for 1902 are presented in Table 1, with such facts as are available for the censuses of 1860, 1870, 1880, and 1890.

Table 1.—*Production of barytes: 1860 to 1902.*

census.	Quantity (short tons).	Value.	Where produced.
1860		$25,000	New York.
1870		100,000	Connecticut.
1880	3,608	37,491	Georgia, Missouri, Pennsylvania, Virginia.
1890 (for calendar year 1889).	21,460	106,313	Missouri, Virginia, Illinois.
1902	61,668	203,154	Missouri, North Carolina, Tennessee, Virginia.

At the census of 1860 the statistics of this mining industry were not separately reported, but were included among those for manufactures. Returns were given for 1 barytes establishment in Westchester county, N. Y., which had 40 employees, who received $12,000 in wages. The cost of materials was given as $5,000, and the value of product as $25,000.

The only statistics reported for this industry at the census of 1870 were those of 1 establishment in New Haven county, Conn., which employed 110 men, all above ground, to whom $78,000 was paid in wages. The cost of materials was $5,518, the capital $50,000, and the value of the product (quantity not stated) $100,000. The deposit, which was located at Cheshire, had been mined quite extensively, as is shown by the old workings.

At the census of 1880 the statistics for barytes were shown under minor minerals, and a total of 6 mines was reported for the states of Georgia, Missouri, Pennsylvania, and Virginia. These employed 63 wage-earners, to whom was paid $7,802 in wages. The cost of materials was given as only $200, making the total cost $8,002 for the production of 3,608 tons, which was valued at $37,491. This is an increase of $12,491 in the value of the production of 1880 over that of 1860.

At the Eleventh Census mining industries were shown separately, and included barytes. The statistics, however, for this mineral were not uniform for the whole country, and are not, therefore, comparable with those for 1902.[1]

The quantity of barytes produced in 1889 was given as 21,460 short tons, valued at $106,313, an increase of 17,852 tons in quantity, and of $68,822 in value, over that for the year 1880. Most of this production was obtained from Missouri and Virginia, with a smaller amount from Illinois.

At the census for the calendar year 1902, the quantity of barytes produced was given as 61,668 short tons, valued at $203,154, which is an increase of 40,208 short tons in quantity and of $96,841 in value, over the production reported at the census of 1890.

In 1902 no product of barytes was reported for New York, Connecticut, Georgia, and Illinois, although these states were returned as producers at one or all of the censuses of 1860, 1880, and 1890.

[1] Barytes mining in Missouri is carried on in such a very irregular manner that it is impossible to obtain any reliable statistics relative to labor and wages. Farmers mine it in off seasons; that is, when there is no farming to do they employ themselves and their hands in getting out the barytes found on their farms, haul it to the nearest tradesman, and receive in exchange dry goods, groceries, or other necessaries, or cash. The farmers thus occupy time which would otherwise be idle, and dispose of the barytes at a less figure than it would pay to mine it systematically. The supply thus obtained is nearly sufficient to keep the mills up to their fullest capacity.

A few mines are, however, operated with some degree of system, though for want of proper records it is necessary to estimate a considerable portion of the matter of labor and wages. The mines altogether give irregular employment to about 580 men. The rate of compensation for foremen is about $2.50 per day, and for laborers from $1 to $1.50 per day. It is rarely, however, that the men make full time, and their daily earnings are reported at from 50 to 75 cents. From 75 to 100 women obtain the same sort of irregular employment, earning about 35 cents per day. Boys get from 25 to 30 cents per day. One mine was active nearly the entire year, but in most cases the number of days worked at the mines ranged from 125 to 200. One mine in Illinois employed 10 men and 2 women for 52 days. (Eleventh Census, Mineral Industries, page 745.)

The large increase in the use of white lead is one of the principal reasons for the increase in the production of barytes. This mineral was formerly considered simply as an adulterant, but it is now beginning to be recognized that it has qualities of its own that make it of value as a pigment, and when it is used in combination with white lead or zinc white, these qualities appear to advantage.

Table 2 is a summary of the statistics for 1902.

TABLE 2.—*Summary: 1902.*

Number of mines or quarries	49
Number of operators	42
Salaried officials, clerks, etc.:	
Number	28
Salaries	$15,159
Wage-earners:	
Average number	336
Wages	$130,285
Contract work	$1,000
Miscellaneous expenses	$35,555
Cost of supplies and materials	$7,772
Product:[1]	
Quantity, short tons	61,668
Value	$203,154

[1] Includes 539 tons, valued at $1,618, the product of two lead mines; the wages and other details are embraced in the statistics for lead.

Of the 49 mines or quarries shown for 1902, 34 are in Missouri, 5 in North Carolina, 6 in Tennessee, and 4 in Virginia. These were controlled by 42 operators, of whom 16 were individuals, 20 firms, and 6 incorporated companies. Each of 2 firms operated 4 mines. Missouri leads in this industry, with 69.4 per cent of the mines and 51.5 per cent of the value of the production. North Carolina is next in respect to the value, with 21.7 per cent, and Virginia third, with 19.5 per cent. Tennessee produced only 7.2 per cent of the total value of the production, although reporting 6 mines, which is 1 more than North Carolina and 2 more than Virginia.

Six mines or quarries were idle during the year, 1 each in Missouri and Ohio, and 2 each in Tennessee and Virginia.

Capital stock of incorporated companies.—Table 3 shows the capitalization and bonded indebtedness of the 6 incorporated companies.

TABLE 3.—*Capitalization of incorporated companies: 1902.*

Number of incorporated companies	6
Capital stock and bonds issued	$1,158,900
Capital stock (all common):	
Total authorized—	
Number of shares	115,050
Par value	$10,983,000
Total issued—	
Number of shares	15,019
Par value	$979,900
Dividends paid	$2,640
Bonds:	
Authorized—	
Number	1,700
Par value	$1,700,000
Issued—	
Number	179
Par value	$179,000
Interest paid	$6,000

Two of these companies were operating in Missouri, 2 in North Carolina, and 2 in Virginia. The entire stock, both authorized and issued, is common stock. A little more than 8.9 per cent, par value, of the authorized stock has been issued and a little more than 10.5, par value, of the bonds. Dividends of $2,640 were paid on $58,000 of the $979,900 capital stock issued.

Employees and wages.—There were at the 49 mines or quarries a total average number of 364 employees, of whom 28, or 7.7 per cent, were classified as salaried employees, and 336, or 92.3 per cent, as wage-earners. Of the total amount, $145,444 reported as paid for salaries and wages by the 42 operators engaged in the production of barytes, $130,285, or 89.6 per cent, was paid to the wage-earners and $15,159, or 10.4 per cent, to the salaried employees. The classification of these 364 salaried employees and wage-earners is shown in Table 6.

Of the 321 wage-earners classified as miners or quarrymen, only 51, or 15.9 per cent, were employed below ground, of which 31 were in North Carolina, 16 in Virginia, and only 4 in Missouri, although the latter state produces over one-half of the total production. This is due to the entirely different occurrence of the deposits of barytes in North Carolina and Virginia as compared with those in Missouri. In the latter state the deposits occur near the surface, so that they can be worked almost entirely by means of pits and open cuts, while those in Virginia and North Carolina have to be worked largely by means of shafts, tunnels, and drifts. There was obtained from those mines reporting wage-earners below ground a production of barytes valued at $62,900, or 31 per cent of the total value. The total underground wage-earners numbered 52, or 15.5 per cent of the total wage-earners, and their wages constituted 12.1 per cent of the total wages paid. The 8 wage-earners shown under "all other wage-earners" are laborers who handle, load, and haul the ore and do miscellaneous work.

There were on an average 7 wage-earners to a mine or quarry. In addition to the number of regularly employed wage-earners, 10 were employed in contract work in North Carolina at an expense of $1,000. They worked altogether a total of one hundred days.

The number of wage-earners employed during each month, and their daily rates of pay, are shown in Table 6. The busiest month of the year for the industry as a whole was the month of May, when a total of 443 wage-earners were at work. August was the next busiest month, with 441. The least active month was December, with 144. Many of the companies in Missouri employ no regular miners, the work being done by the farmers of the neighborhood who work in the mines at odd times. The company pays them for the ore dug, whether it comes in small or large quantities, or whether by bucket, sack, barrel, or wagon load. Of the total number of wage-earners 321, or 95.5 per cent, are classed as miners. Of this number the wages of 135, or 42.1 per cent, ranged from $1 to $1.24 per day, and those of 66, or 20.6 per cent, ranged from $1.75 to

$1.99 per day. The miner who received from $0.50 to $0.74 a day was employed in Virginia. The prevailing wages for all classes of wage-earners was from $1 to $1.24 a day, there being 143, or 42.6 per cent, paid at this rate.

Supplies, materials, and miscellaneous expenses.—The amount expended for supplies and materials was $7,772. Of the miscellaneous expenses, amounting to $35,555, $27,300, or 76.8 per cent, was expended for royalties and rent of mines and mining plant, the remainder being for rent of offices, taxes, insurance, interest, and other sundries.

Mechanical power.—Of the 42 operators from whom returns were received only 2 reported that power was required for the operation of their mines. These were in North Carolina and Virginia. The total horsepower amounted to 110, furnished by 3 steam engines.

Production.—The total production of barytes for the calendar year 1902 was 61,668 short tons, valued at $203,154, of which Missouri produced 31,334 short tons, or 50.8 per cent of the total; North Carolina, 14,679 short tons, or 23.8 per cent; Tennessee, 3,255 short tons, or 5.3 per cent; and Virginia, 12,400 short tons, or 20.1 per cent. A comparison of the production for this industry since 1889 is shown in the following table, which gives the statistics relating to the quantity and value of barytes, as published by the United States Geological Survey:

TABLE 4.—*Production of barytes: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

YEAR.	Quantity (short tons).	Value.	Average value per ton.
1889	21,460	[1] $106,313	$4.95
1890	21,911	86,505	3.95
1891	31,069	118,363	3.81
1892	32,108	130,025	4.05
1893	28,970	88,506	3.06
1894	23,335	86,983	3.73
1895	21,529	68,321	3.17
1896	17,068	46,513	2.73
1897	26,042	58,295	2.23
1898	31,306	108,339	3.50
1899	41,894	139,528	3.33
1900	67,680	188,089	2.78
1901	49,070	157,844	3.22
1902	61,668	203,154	3.29

[1] Value includes floated barytes when sold first in that form.

As shown by the above table, there was an increase of 12,598 tons in quantity and of $45,310 in value in the production of 1902 over that of 1901. Of the 1902 production 539 tons, valued at $1,618, were obtained as a by-product from 2 lead mines; and the salaries, wages, and other expenses of these mines are credited to the lead industry.

The largest production reported for this industry was in 1900, when it amounted to 67,680 short tons. In value, however, 1902 leads with a valuation of $203,154, while that of 1900 was $188,089. This is due to the higher average price received per ton for the barytes in 1902, which was $3.29, or 51 cents more than the average price of $2.78 per ton received in 1900. The total quantity of barytes produced in the United States since 1882 is 622,950 short tons, an average production of 29,664 tons per year.

The highest average value reported in the table for any year was $4.95 in 1889, and the lowest $2.23 in 1897. In 1902 the price per ton reported varied from $1.65 to $4.50, but the average was $3.29 per ton.

In 1902, there were imported barytes, manufactured and unmanufactured, to the value of $51,711, and other barium compounds, nearly all of which could be made of domestic barytes, to the value of $152,361. The imports of barytes from 1889 to 1902, inclusive, as published by the United States Geological Survey, are shown in the following table:

TABLE 5.—*Imports of barytes: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

YEAR ENDING DECEMBER 31—	MANUFACTURED.		UNMANUFACTURED.	
	Quantity (short tons).	Value.	Quantity (short tons).	Value.
1889	1,801	$22,458	6,785	$7,660
1890	1,563	16,453	4,815	13,133
1891	2,149	22,041	2,900	8,816
1892	1,389	15,419	2,789	7,418

1902	3,908	37,389	3,929	14,322

Table 6 is a detailed summary of the statistics of the barytes industry for 1902.

DESCRIPTIVE.

The first mining for barytes in the United States was very probably in Westchester county, N. Y., prior to 1860, and this was followed in the next decade, 1860 to 1870, by the opening of the mine at Cheshire, New Haven county, Conn. Between 1870 and 1880 barytes deposits had been opened in Georgia, Missouri, Pennsylvania, and Virginia, while those of New York and Connecticut had ceased to be producers. Between 1880 and 1890 Illinois had been added to the states producing this mineral, and during the next decade, from 1890 to 1900, North Carolina and Tennessee became producers, and in 1902 deposits of this mineral began to be developed in Kentucky. This makes a total of 9 states in which this mineral has been found in commercial quantity. In 1902 Missouri, North Carolina, Tennessee, and Virginia were producers of this mineral, with known deposits in Illinois and Kentucky, which are being developed, with the expectation of putting their product on the market in 1903. The Missouri deposits are fur-

nishing more than one-half of the barytes mined in the United States. They are located in Cole, Crawford, Miller, St. Francois, and Washington counties, with by far the larger proportion of the mines in the last-named county. There are a number of deposits in these five counties that probably contain barytes in quantity, but on account of their distance from the railroad they are not mined to any great extent at the present time. The mineral is found for the most part associated with limestone. This rock is often altered and decomposed to some depth, leaving a residual clay-like material in which the barytes, which has resisted the alteration, is found. Sometimes the barytes is encountered close under the grass roots. The lead ore, galena, is associated more or less with the barytes, and it makes a very valuable by-product, although occasionally a deposit is found that is practically free from this mineral. Where the barytes is encountered near the surface in the clay, it is apt to be stained more or less with iron oxide.

In North Carolina the barytes deposits occur in Gaston, Madison, and Orange counties, those which were worked most extensively during 1902 being in Madison county. The mining in this state is largely by means of shafts, tunnels, and drifts.

The Tennessee barytes deposits are located in Bradley, Cocke, Greene, Loudon, and Monroe counties, but during 1902 the production of this mineral was much less than the year before. The erection, however, of a large barytes mill for grinding this mineral and preparing it for market, and also for the production of artificial sulphate of barium, and other compounds of barium, will undoubtedly lead to a considerable increase of the industry in this state.

In Virginia the barytes mines are located in Bedford, Campbell, Louisa, Pittsylvania, Russell, and Tazewell counties. The mines near Evington, Campbell county, where the mining is now carried on largely by means of shafts and drifts, have been worked almost continuously since 1874. About 1901 the deposits of Russell and Tazewell counties were opened, and the latter gives prospect of becoming the largest producer of this mineral in Virginia.

The deposits of barytes that are being developed in Illinois are in Hardin county, and those of Kentucky are in Crittenden county.

The growth of this industry has been partially dependent on the growth of the paint industry, in which a very large proportion of the barytes produced is used. The barytes has a pure white color, which is permanent, and it is unaffected by weather or by gases that in some instances blacken white lead, for which the barytes is used as a substitute. Besides the use of barytes in the paint industry, it is employed in the manufacture of paper and rope to give weight; and also in the preparation of a material that is used to coat the canvas sacks in which hams are wrapped when ready for market. Another use for this mineral, and one that should increase rapidly, is in the manufacture of other barium compounds, principally the hydroxide. This compound was formerly prepared almost exclusively from the mineral witherite, barium carbonate; but on account of its rare occurrence in commercial quantity, barytes has begun to be the raw material used in the manufacture of this hydroxide and other salts of barium. One of the greatest uses of the barium hydroxide will perhaps be in the beet sugar industry, for the separation of the sugar left in the molasses. It is also claimed that the compound is applicable in the cane sugar industry. Other uses considered for it are in the purifying of water used in steam boilers and in the preparation of hides for tanning. As these uses of barium hydroxide increase there should be a larger demand, and consequently a larger production of barytes.

These multiplying uses for barytes put the industry on a new basis, and take the mineral out of the list of adulterants with which it has been usually classified.

TABLE 6.—DETAILED SUMMARY: 1902.

	United States.	Missouri.	North Carolina.	Tennessee.	Virginia.
Number of mines or quarries	49	34	5	6	4
Number of operators	42	28	5	6	3
Character of ownership:					
Individual	16	10	.....	5	1
Firm	20	16	3	1	.....
Incorporated company	6	2	2	.....	2

MINERAL PIGMENTS, CRUDE

MINERAL PIGMENTS, CRUDE.

By Joseph Struthers, Ph. D.

As early as 1850 the census statistics of ocher, which is a subclassification of crude mineral pigments, appeared among statistics of manufactures. There were only 2 establishments, and they were in Vermont. In 1860, 1 establishment was shown, also among manufacturing statistics, in Berkshire county, Mass. A census of mining industries was taken at the census of 1870, and ocher was included among stone quarrying industries. There were 4 establishments, all in Bennington county, Vt. Among the mining industries at the census of 1880, 7 establishments were given—1 in New Jersey and 3 each in Vermont and Virginia—but, according to a footnote, there were a few ocher mines in Virginia or West Virginia from which no returns were received.

At the Eleventh Census statistics were given among mineral industries for ocher and metallic paint. The number of establishments was not stated. The states of Alabama, Colorado, Georgia, Maryland, Massachusetts, Pennsylvania, Vermont, Virginia, and Wisconsin were shown for ocher, and Alabama, Colorado, New York, Ohio, Pennsylvania, Tennessee, and Wisconsin for metallic paints. The statistics were for the year 1889 and apparently included statistics of the manufacture of ores into marketable paints.

The substances included in this report, under the title "Mineral pigments, crude," are: Iron ores, hematite, or red iron ore (Fe_2O_3), and limonite of brown iron ore (Fe_2O_3, $3H_2O$); clay and other earths, comprising ocher (yellow, gray, and brown) umber (including Spanish brown), and sienna; soapstone, slate, and shale, utilized for making certain shades of gray pigment; and gypsum, or mineral white, used as a pigment for printing wall paper.

Table 1 presents comparative statistics for the industry for 1902, 1889, 1880, and 1870.

Table 1.—*Comparative summary: 1870 to 1902.*

	1902	1889[1]	1880[2]	1870[2]
Number of mines or quarries	35	(3)	7	(3)
Number of operators	35	(3)	(3)	4

Quantity, short tons	35,479	36,184	4,037	(3)
Value	$360,885	$463,766	$135,840	$15,000

[1] Ocher and metallic paint only.
[2] Ocher only.
[3] Not reported.
[4] The United States Geological Survey reports 73,049 short tons of mineral paints, manufactured and sold, valued at $944,332. Census figures are for the crude mineral pigments.

The 35 mines reported for this industry in 1902 were controlled by 22 incorporated companies, 8 individuals, and 5 firms. The state of Pennsylvania led in production, having 58.6 per cent of the total quantity and 68.3 per cent of the total value; the state of Georgia was next, with 16 per cent of the quantity and 13.4 per cent of the value; Maryland had 7.1 per cent and 3 per cent, respectively; New York reported 3.6 per cent of the quantity and 1.2 per cent of the value, leaving for all other states 14.7 per cent and 14.1 per cent, respectively.

There were 13 mines reported idle during 1902, controlled by 6 incorporated companies, 4 firms, and 3 individuals. The 6 incorporated companies issued capital stock and bonds to the par value of $86,750, the total amount authorized being $96,750. Three of the mines were in California, 2 each in Georgia and Missouri, and 1 each in Alabama, Michigan, Ohio, Pennsylvania, Tennessee, and Vermont. From these 13 mines miscellaneous expenses to the amount of $36 were reported. The total horsepower of the engines at these idle mines was

given as 115—3 steam engines having a total of 95 horsepower and 1 water wheel with 20 horsepower.

Capital stock of incorporated companies.—The details of capital stock and funded debt are shown in the following table for 17 of the 22 incorporated companies controlling active mines. The figures for the remaining 5 companies are omitted because mining is but a small part of the total business of each.

TABLE 2.—*Capitalization of incorporated companies: 1902.*

[1] Includes companies distributed as follows: Arkansas, 1; California, 1; Missouri, 2; New York, 2; Virginia, 1; Wisconsin, 1.
[2] Includes companies distributed as follows: Arkansas, 1; Missouri, 2; New York, 1.

Ten of the incorporated companies were in Pennsylvania, 4 in Georgia, 2 each in Missouri and New York, 1 each in Arkansas, California, Virginia, and Wisconsin. The capital stock and funded debt of the Pennsylvania companies was 68.7 per cent of the total. The par value of the capital stock issued by all the companies was 63 per cent of the total par value authorized. The bonded indebtedness was 6.9 per cent of the capital stock and funded debt. The dividends paid amounted to 1.3 per cent of the total stock issued and 3.4 per cent of the total stock on which they were declared. Eighty-nine and five-tenths per cent of the total amount paid in dividends was declared on common stock and 10.5 per cent on preferred. Of the total dividends, 86.9 per cent was paid on the stock of the Pennsylvania mines and 13.1 per cent on the stock of the mines of "all other states."

Employees and wages.—The wage-earners were 80.3 per cent of the salaried employees and wage-earners, and their wages were 66.4 per cent of the total salaries and wages. There were 7.3 wage-earners to a mine. Of all the states, Pennsylvania had by far the largest number of wage-earners, leading with 57.8 per cent of the total number and 63.2 per cent of the total wages paid. Georgia was next with 25.4 per cent of the wage-earners and 18.4 per cent of the wages paid, the remainder being divided between Maryland, New York, and "all other states." Of the total number of wage-earners in all the mines, 20.3 per cent were underground. Pennsylvania had 78.8 per cent of these underground workers and Georgia the remainder, or 21.2 per cent.

The average number of wage-earners employed during each month and their daily rates of pay by occupations are shown in Table 3. The number varied little the year through. The busiest months were apparently September and October, and the least busy, February and March.

No particular skill or experience is required on the part of a miner in this industry, therefore the rates of pay should not be compared with those reported for miners where greater skill is necessary. The mines are worked by open pits, shafts, or tunnels, and in some cases the ore is ground, floated, dried, or otherwise prepared for market at the mines. Of the total number of wage-earners, 90, or 35.2 per cent, are classed as miners or quarrymen, and 102 as "all other wage-earners." Of the 90 miners, 24 received from $1.50 to $1.74 per day; 23 from $1.25 to $1.49; and 21 from $0.75 to $0.99. Of the "all other wage-earners" reported, 32 received from $1 to $1.24 per day and 31 from $1.50 to $1.74. These men are employed doing miscellaneous work around the quarries, sorting the ore, washing and hauling it, etc. The rate of pay of the largest number, 86, for all occupations was from $1.50 to $1.74 per day. Those receiving the highest daily rate of pay were engineers, machinists, etc.

Supplies, materials, and miscellaneous expenses.—The amount, $58,073, reported as paid for supplies and materials, is the largest expenditure for any one item excepting wages. Of the amount, $24,893, reported for miscellaneous expenses, $13,326, or 53.5 per cent, was expended for royalties and rent, and $11,567, or 46.5 per cent, for rent of offices, taxes, insurance, interest, and other sundries.

Mechanical power.—Of the 35 operators from whom reports were received, 21 reported the use of power, the total being 1,840 horsepower. Of this, 1,200 horsepower, or 65.2 per cent, was steam; 550, or 29.9 per cent, water wheels; 50, or 2.7 per cent, hydraulic pump; and 40, or 2.2 per cent, gas or gasoline. Of the steam, 545 horsepower, or 45.4 per cent of the total, was used in Pennsylvania; 185, or 15.4 per cent, in Georgia; and the remainder, 470, or 39.2 per cent, in Maryland, New York, and "all other states." Of the water wheels, 500 horsepower was employed in Pennsylvania and 50 in New York. "All other states" had all the gas or gasoline horsepower, and Georgia the hydraulic pump.

Production.—The United States Geological Survey has published annual statistics concerning the quantity and value of mineral paints, beginning with 1894, and of some of the subclassifications from various dates, but these statistics are not comparable with those of the census, for the reason that they include the manufacture of the ore into paints and are not limited to the value of the crude ore at the mines. The Census statistics for 1902 include only that part of the manufacture which is done at the mines and which it is impossible to segregate, the mining and manufacture being in such cases accomplished with the same capital and under the same management. From the reports received for 1902, the various ores and clays from which mineral paints were made ranged in value from $1 (for red rock pigment) to $80 (for zinc white) per ton. The average value per ton was $10.17. Allowance must be made for the great variation in the average value due to the comparatively wide range in quantities and materials. The classification of crude mineral pigments includes yellow, gray, and brown ocher, umber, sienna, zinc white, white mineral (gypsum), slate (sold for pigment), carbonate of iron and of zinc, oxide of iron, and other pigments. With ocher some of the previous censuses have included a little of umber and sienna. Ochers are known as those clays to which the natural mixing of iron peroxide and water has imparted a bright red or reddish-yellow color, while the iron pigments are those from which the darker red or brown paints are made. In the statistics of production given at the census of 1902, there are by-products of 390 tons of soapstone used for pigment, valued at $2,340, and 18 tons of slate, valued at $525. The capital, wages, and other expenses attending the production are given under "Talc and soapstone" and "Slate."

A detailed summary showing the statistics for crude mineral pigments during 1902 is given in Table 3.

DESCRIPTIVE.

Pigments are substances, both natural and artificial, which are usually insoluble in water, oils, and other neutral solvents, and are used to impart color to a body either by surface adhesion or by direct admixture with its substance. Generally there is no chemical combination between the pigment and the body it covers. When mixed with a drying oil, or with water containing oil or size, the pigments form the basis of paint which is used for decorative or protective purposes.

The natural pigments, the only ones with which this report is concerned, are among the most important but are fewer in number than those prepared artificially by chemical precipitation or other processes. According to Thorp[1] the chief pigments are classified as follows:

Whites: White lead, lead sulphate, lead oxychloride, zinc white, zinc sulphide, barytes, gypsum, and whiting. *Blues:* Ultramarine, Prussian blues, smalt, cobalt blues, copper blues, and indigo. *Violet:* Ultramarine. *Greens:* Ultramarine, Brunswick green, chrome green, Guignet's green, copper greens, and copper and arsenic greens. *Yellows:* Chrome yellow, yellow ocher, cadmium yellow, orpiment, litharge, gamboge, and Indian yellow. *Orange:* Orange mineral, chrome orange, and antimony orange. *Reds:* Red lead, chrome red, red ocher, Venetian red, vermilion, realgar, antimony red, and carmine. *Browns:* Umbers, Vandyke brown, and sepia. *Blacks:* Lampblack, ivory black, boneblack, and graphite.

Iron oxide pigments.—The iron oxide pigments are used to make dark red or brown paints, being known in the trade as "natural reds." They are classed as natural and artificial, the former (metallic paints and mortar color) being chiefly made from brown iron ore and ferruginous shales, and the latter (Venetian red, Tuscan red, and Indian red) from calcining copperas or copperas residues in a furnace yielding ferric oxide (Fe_2O_3) in a state of very fine division.

Although the occurrence of iron ores in the United States is widespread, and enormous deposits exist at many places, there are very few localities in which the material is of suitable physical and chemical composition for manufacture into metallic paint.

The ores reported for use in the manufacture of metallic paint and mineral paint were mined in Anne Arundel and Baltimore counties, Md.; Carbon county, Pa.; James county, Tenn.; Rutland county, Vt.; Bedford county, Va.; and Dodge county, Wis. The mortar colors were all reported from Northampton county, Pa. Other iron pigments reported were mined in Cattaraugus county, N. Y., and Carbon and Wyoming counties, Pa. The Venetian red reported was all mined in Anne Arundel county, Maryland.

The iron oxide paints are highly esteemed for some purposes on account of their freedom from poisonous ingredients which are found in some mineral paints, and because they resist to a marked degree the effects of light, heat, and moisture, a quality which renders them of great value for outside or exposed work. Ochers in addition resist the destructive action of salt air, and are therefore of special value in localities at or near the seacoast.

A certain proportion of metallic paint is used as a coloring matter in mortar making, and appears in some classifications under the title "mortar colors."

The mining and preparation of the crude ore for the market are very simple processes. The ore, generally obtained by open-cut or quarrying methods, is disintegrated by exposure to the atmosphere, carried to a mill, roughly crushed, dried, pulverized, and passed over a screen of bolting cloth or through some type of pneumatic separator, from which the final product is classified and packed for shipment. At times the ground ore is

[1] Outlines of Industrial Chemistry, by F. H. Thorp. New York Macmillan & Co., 1898.

levigated and the settled products dried and packed for shipment.

Ochers.—The name ocher is applied to clays and other earthy bases containing in their natural state sufficient ferrous or ferric oxide or hydroxides to impart to the mass a bright red or yellowish-red tint. The color varies from a golden yellow to a dark red, occasionally possessing various tints of blue and green.

The ochers reported were mined in Clay county, Ark.; Calaveras and Stanislaus counties, Cal.; Bartow and Richmond counties, Ga.; Berks, Lehigh, Luzerne, and Northampton counties, Pa.; Rutland county, Vt.; and Page county, Va. The sienna reported was mined in Washington county, N. Y., and the umber in Lawrence county, Pennsylvania.

The ochers have been used as paints from a very early date, the oldest applications positively recognized having been made in Italy, though it is believed that some varieties were in use still earlier by the Egyptians and Greeks. In modern times the ochers were first mined and prepared in Italy, and the siennas and umbers derive their names from the Italian towns in which they were manufactured into pigments.

Ochers are classified in many ways, according to the locality of occurrence, the composition, and the special shade of color. Practically they may be grouped into yellow, red, and brown. Yellow ocher is that which is colored by a ferric hydroxide. Red ocher owes its tint to ferric oxide, and it is therefore evident that red ocher may be prepared artificially by expelling the water from yellow ocher by calcining in a furnace or kiln. Brown ocher is red ocher modified by the presence of black manganese dioxide, which in various proportions yields a large range of brown colors, notably sienna brown, umber, Vandyke brown, and manganese brown.

The variation of ocher in shade and in quality depends chiefly, but not entirely, upon the proportion of iron oxide present as well as the quantity of water combined with the iron oxide. A red ocher, improperly called iron minium, very rich in iron oxide, is made by calcining and pulverizing limonite that is free from clay.

There are few pigments more free from adulteration than the ochers, for the reason that any filler that can be used advantageously is more costly than the ocher itself. Sometimes a little chrome yellow is added in order to improve the tone of a poor colored ocher, but the presence of this adulterant is very easily detected. Oxford ochers are the brightest and best of the mineral pigments of this class. They are obtained from Oxford, England. The German pigments are often called ochers, although improperly so, for the reason that they are ligneous earths and not ferruginous clays. The manufactured product varies greatly in quality and value, and some of the grades pass insensibly into umber or sienna.

Umber and sienna in reality are varieties of ocher which have been isolated on account of the brown color which is imparted to the natural clay material by the addition of iron and manganese oxides; raw umber is of a brown color, while burnt umber is of a somewhat richer and redder hue. Raw sienna is of a brownish yellow shade which affords a rich russet brown when burned. Intermediate shades of color are obtained by mixing natural products with various properties of iron and manganese oxides, and sometimes by mixing both raw and calcined materials together.

The mining and preparation of ochers, umbers, and siennas are similar to the practice described under iron oxide pigments, with the exception that at times the ground product, in part or wholly, is first heated in a furnace until the desired color has been obtained. In place of levigating and settling the ground material, it is sometimes passed through a pneumatic separator which yields an impalpably fine and uniform product.

Slate, shale, and soapstone.—A few tons each of slate, shale, and soapstone (the last-named being a variety of the mineral talc) are annually ground in the United States to produce a gray-colored pigment used chiefly as a filler for mineral paints, especially those of the variety called fire-retarding.

Gypsum.—Known also as terra alba and mineral white, is a natural hydrated calcium sulphate ($CaSO_4$, $2H_2O$). It is used to a minor extent as a pigment for printing wall paper. The method of making this pigment consists in grinding the mineral and treating it with acid in order to remove any tint or color resulting from the presence of iron oxide. The gypsum, or white mineral reported in 1902 was mined in Cape Girardeau county, Missouri.

Artificial pigments.—In addition to the natural iron oxide pigments, made by a simple washing and grinding of pure crude ores, there are two very important artificial iron oxide pigments made by roasting the residuum obtained from making copperas, or green vitriol ($FeSO_4$,$7H_2O$). One is Venetian red, composed almost wholly of artificial iron sesquioxide, and the other Indian red, which is comprised of about 40 per cent of iron sesquioxide, the balance being mainly calcium sulphate, made by adding a certain proportion of lime during or before the roasting.

There are two methods of manufacturing these artificial reds, the "dry" and the "wet." In the former method, which is the cheaper for the low grades of oxides, the impure copperas is roasted in a furnace with lime or similar material, in order to neutralize the acid in the sulphate until the desired strength and color of the product are obtained. Occasionally copperas alone is roasted until the acid constituent has been completely expelled, leaving the residuum in the form of pure iron sesquioxide; a filler (whiting or gypsum) is then added in proportions to yield the desired grade of Venetian red, some containing as little as 10 per cent of iron oxide or coloring power.

The wet method is cheaper for the manufacture of the general grades of Venetian red, but yields a less uniform product than the dry method. In principle, the waste liquor from the cleansing or pickling process in preparing iron wire or plates for galvanizing by immersion in weak sulphuric acid is treated direct by the addition of milk of lime, sodium carbonate, or similar reagents, which precipitates the iron as a hydrate or carbonate to the bottom of the tank. This precipitate is subsequently separated from the liquor by filtration through a press, the dried cakes remaining therein being subsequently roasted in furnaces, cooled, and packed for the market without grinding. The product made in this manner is not uniform in quality, and has but a limited use.

Hematite ore is sometimes ground and sold as Venetian red. The natural products, however, are inferior to the artificial and do not command as high a price.

Formerly the iron oxide pigments made in the United States did not contain more than 50 per cent of iron oxide, the higher grades being imported. Recently, however, the use of a crucible furnace of special design, which gives good control of the heat and of the oxidation, has raised the grade of the product to practically 100 per cent of iron oxide.

Improvements have also been made in the wet process, chiefly in the substitution of mechanical appliances for hand labor, which has lessened the cost of production and given a more uniform product.

Other mineral pigments.—Among other minerals used in part in the manufacture of paints are barytes, asbestos, graphite, and asphaltum.

The mineral is generally prepared as follows: The crude ore is hand sorted and the limestone rock and other foreign materials removed; the selected ore is then crushed and boiled in dilute sulphuric acid in order to remove any remaining impurities, chiefly iron oxide, which may impart a tint or color to the product. The material is then thoroughly washed after boiling to free it from acid or soluble salts and is finely ground and put on the market in four varieties: No. 1, No. 2, No. 3, and "floated" or water sorted.

Barium sulphate, known as "blanc fixe," which has been precipitated artificially as a by-product in some chemical industries, is used to a considerable extent as a filler and pigment. It has more body and greater capacity and covering power than the native mineral barite, for the reason that it is amorphous while barite is crystalline.

The chief use of barite is as a pigment which is usually mixed with white lead. In the United States it is regarded as an adulterant which depreciates the value of the paint, but in Europe it is considered a valuable addition, and in many cases a pigment composed of a mixture of barite and white lead is considered more serviceable than white lead alone, for the reason that, owing to the insolubility of barite in acids, it imparts elasticity to the mixture, gives a greater body to the paint, and resists the influence of the weather better than white lead alone.

A considerable quantity of barite is used in the form of lithophone, which is an artificial compound of barium sulphate, zinc oxide, and zinc sulphide, obtained by precipitating zinc sulphide and barium sulphate by a mixture of solutions of zinc sulphate and barium sulphide, the precipitate being washed, dried, and calcined. A type composition is given as: Barium sulphate, 68 per cent; zinc oxide, 7.2 per cent; and zinc sulphide, 24.8 per cent. The composition, however, varies with the different makes.

Asbestos can hardly be classed as a pigment, although when used as a filler its white color lightens the color of the material to which it is added. The chief use of asbestos in paint manufacture is to yield a so-called noninflammable or fireproof paint. The fibrous varieties of talc are also used for this purpose. Only a small proportion of the total production of asbestos in the United States is utilized in paint manufacture.

Both the natural mineral and the artificial product made in the electric furnace are used as a black pigment and in pencils, crayons, and in stove polish. The color of the pigment is a dull black and permanent, and on account of its resistance to the action of the atmosphere, as well as that of ordinary chemicals, it is of great value as the basis of a protective paint for coating oxidizable metals, chiefly iron and steel.

The purer grades of asphaltum are largely used as a basis for the manufacture of a black varnish, and as a protective paint for the interior of chlorine stills, bleaching powder chambers, acid tanks, and like apparatus. Asphaltum is not acted upon by ordinary chemicals, and for this reason it is invaluable for protecting structures of iron, steel, and even wood, which would be rapidly destroyed by acid fumes unless coated with some inert material.

Whiting, or Paris white, is composed of calcium carbonate ($CaCO_3$). Calcium carbonate occurs quite extensively in nature, either in the crystalline form, as the well-known mineral calcite, or calc-spar, or in the compact form, such as marble and limestone, or as the soft compact variety known as chalk. It is produced artificially as a by-product of many chemical operations. The whiting used in commerce is generally prepared by grinding and levigating pure chalk, large deposits of which occur, notably in England and France. The chief use of whiting as a pigment is to modify the shade of other pigments. It is also largely used as a basis for whitewash, and when mixed with from 15 to 18 per cent of linseed oil it forms putty.

STEEL HARDENING METALS

30223—04——61

STEEL HARDENING METALS.

By Joseph Hyde Pratt.

Under the head of steel hardening metals are included those metals used or experimented with in the hardening of steel, although some of them are used more generally for other purposes in the form of compounds. The metals belonging to this class are nickel, chromium, tungsten, molybdenum, titanium, uranium, and vanadium. The statistics in this report relate to the production of the ore from which these metals are obtained, except that the figures for nickel and cobalt are for the matte made at the mines. In the mineral classifications, chromium appears as chrome ore, nickel as nickel and cobalt, and titanium as rutile. Manganese naturally comes under the head of steel hardening metals; but, on account of its comparatively large production, it is treated separately. Nickel and chromium have been presented separately at former censuses, but the statistics of the remaining metals have not been previously shown.

The statistics collected at the census of 1902 for the steel hardening metals are summarized in Table 1.

Table 1.—*Summary: 1902.*

	Total.	Tungsten.	Uranium and vanadium.	All other steel hardening metals.[1]
Number of mines	12	4	3	5
Number of operators	12	4	3	5
Salaried officials, clerks, etc.:				
Number	3		2	1
Salaries	$3,740		$3,500	$240
Wage-earners:				
Average number	26	2	19	5
Total wages	$20,911	$1,260	$17,040	$2,611
Contract work	$825			$825
Miscellaneous expenses	$735	$120	$490	$125
Cost of supplies and materials	$3,652	$210	$3,010	$432
Product:[2]				
Quantity, short tons	4,444	184	3,810	450
Value	$83,717	$5,975	$48,125	$29,617

[1] Includes operators as follows: Chrome ore, 1; molybdenum, 1; nickel and cobalt, 2; and rutile, 1.

[2] The United States Geological Survey does not report the value of tungsten and molybdenum, nor does it under this classification present the other metals. The report for nickel is for the refined; for cobalt, the oxide prepared from the ore; while Census figures are for the nickel and cobalt matte at the mine.

Besides the mines reporting a production during 1902, 7 were idle. These have been worked to some extent during the past few years, some of them becoming producers, while at others the work has been that of development to prove the existence of ore in quantity. The uncertainty of the demand for most of the ores has been the principal cause of their nonproduction. These idle mines were distributed, by states, as follows: Arizona, 1; California, 1; Colorado, 3; Nevada, 1; and Wisconsin, 1. They were owned by 5 individuals and 2 incorporated companies.

The total number of mines operated in 1902 was 12, distributed among 7 states, as follows: California, 1; Colorado, 6; Connecticut, 1; Missouri, 1; Oregon, 1; Virginia, 1; and Washington, 1. Of these 12 mines, 4—3 in Colorado and 1 in Connecticut—produced tungsten, and 3—all in Colorado—produced uranium and vanadium. Where there are less than 3 operators mining any one ore they are included in "all others." Of the 12 operators engaged in the production of these metals, 8 were individuals, 1 a firm, and 3 incorporated companies.

The total value of the outstanding capital stock of two of the incorporated companies was $200,000, with no bonded indebtedness. The entire authorized stock, all of which is common, has been issued, the shares numbering 1,001,000.

Of the three incorporated companies, one which produced nickel and cobalt, is not included in this table, for the reason that lead was its principal product, nickel and cobalt being merely by-products, and accordingly all statistics for this company, with the exception of the quantity and value of the nickel and cobalt produced by it, are included in the report on lead.

Production.—The total production of these various ores reported in 1902 was 4,444 short tons, valued at $83,717. Of this production 85.7 per cent of the quantity and 57.5 per cent of the value consisted of uranium and vanadium, the remainder being about 1 part tungsten and 3 parts "all others." In quantity the production of chrome ore was second, or next to uranium and vanadium, but in value was fifth. Tungsten ranked third in quantity and fourth in value; rutile, fourth in quantity and sixth, or lowest, in value; nickel and cobalt, fifth in quantity and third in value; while molybdenum, ranking lowest in quantity, was second in value.

The nickel and cobalt ores were concentrated into a matte which was valued at $352 per ton, of which value about five-sevenths was due to the cobalt contents and two-sevenths to the nickel.

The average value per ton received for the chrome ore in 1902 was $14.50. A standard chrome ore contains 50 per cent of chromic oxide (Cr_2O_3), but for every unit above this there is an increase in value of from 75 cents to $1 per ton; while, on the other hand, there is a much greater deduction for every unit below 50 per cent. For some uses, as in the lining of furnaces, chrome ores as low as 40 per cent of chromic oxide can be used.

The reported value of crude tungsten ores varied from $4.68 to $45 per ton. Before this ore is put on the market it is more or less concentrated. An ore containing from 60 to 70 per cent of tungstic oxide will bring in the general market, from $102 to $200 per ton.

Molybdenum ores have been valued at from $100 to $1,500 per ton, but the actual market value for these ores, when they are in constant demand for manufacturing purposes, will be nearer $100 per ton for a 50 to 55 per cent ore free from copper.

The value of uranium and vanadium ores is about $12.63 per ton for crude ore, which averages from 5 to 9 per cent of the oxides. When concentrated, these ores will bring as high as $320 per ton, the prices varying with the percentage of uranium and vanadium oxides.

The titanium reported at the census of 1902, which was all in the form of rutile, was valued at $12.50 per ton, this representing a crude product which had not in any way been concentrated or selected.

Table 2 shows the production of nickel and cobalt oxide in the United States from domestic ores from 1889 to 1902; also imports and exports of nickel oxide and matte. Most of the imports are from Canada, in the form of matte, the refining being done in this country. The exports are largely to the United Kingdom.

TABLE 2.—PRODUCTION OF NICKEL AND COBALT OXIDE FROM DOMESTIC ORES, AND IMPORTS ENTERED FOR CONSUMPTION: 1889 TO 1902; ALSO EXPORTS: 1894 TO 1902.

[1] Includes 35,000 pounds of nickel from Canadian mattes.

[2] Last six months; not separately classified prior to July 1, 1894.

The production of metallic nickel, from 1889 to 1902, in the principal producing countries of the world is given in Table 3. The French manufacturers obtained the ore from New Caledonia, Oceania, and the German from New Caledonia and Norway.

1902	10,693,410	5,025,903	.....	.....	.....	.....

Small quantities of tungsten ore (wolframite) and of tungsten iron, valued at $7,046, were imported during 1902.

The uranium and vanadium ores are mostly exported. Salts of the metals to the value of about $15,000 have been annually imported. The value of these imports for 1902 was $12,491.

Employees and wages.—The aggregate number of all classes of employees and wage-earners, as given in Table 5, was 29, who received $24,651 in salaries and wages. Of these, 3 were classified as salaried employees, receiving $3,740 in salaries; and 26 as wage-earners who were paid $20,911 in wages. Included with the 3 salaried employees was 1 foreman, employed underground, who received $1,500 salary. Of the 26 wage-earners, 15 were employed underground, all of whom were classified as miners. To this number of underground workers should be added the foreman classified as a salaried employee, which would make the total number of underground employees 16.

The wages received by these 26 wage-earners varied from 75 cents to $3.24 per day; 17, or 65.4 per cent of the total number, received from $3 to $3.24 per day. That relatively high wages were paid to these wage-earners is due to the fact that most of the mining of steel hardening metals was in the Western states. The month in which the largest number of wage-earners was employed was July, when the number reached 42. The minimum was in January, when only 15 were employed.

The production of chrome ore in the United States and the imports of chrome ore, chromate, etc., from 1889 to 1902, inclusive, are given in the following table:

TABLE 4.—PRODUCTION OF CHROME ORE IN THE UNITED STATES, AND IMPORTS OF CHROME ORE, CHROMATE, ETC.: 1889 TO 1902.

1902	315	4,567	39,570	582,597	.....	.....	90,817	11,115	593,712

The total amount paid for supplies and various other expenses was $5,212. Of this amount $3,652 was for supplies and materials, and $735 for rent of offices, taxes, etc. The balance of $825 was paid for contract work.

The total amount of mechanical power used in the production of the ores of these steel hardening metals was 310 horsepower, 250 of which was furnished by 6 steam engines and 60 by water wheels. All the water-power was rented.

A detailed summary showing the statistics of the production of steel hardening metals during 1902 is given in Table 5.

DESCRIPTIVE.

CHROME ORE.

Chrome ore, or chromite, which contains the metal chromium, was the first of the minerals containing any of these steel hardening metals to be mined in the United States for commercial purposes. The discovery of chrome ore in this country was made about 1820[1] by Isaac Tyson, jr., at Bare Hills, Md., 7 miles north of Baltimore, but the deposit, being scanty and poor, was soon abandoned. He afterwards found the mineral at Soldiers Delight, about 15 miles northwest of Baltimore. In 1827 his attention was attracted by the appearance in the market place of Baltimore of a man from back in the country who had in his wagon several lumps of a heavy black mineral which he was using to keep a barrel from rolling about in his cart.[2] Upon testing these lumps, Mr. Tyson found the mineral to be chromite and learned that it was from Harford county, about 27 miles from Baltimore. This was the beginning of chrome mining in this country and of the chrome industry of the Tysons, which was later supplemented by manufacturing processes and has continued down to the present time. In the next year, 1828, chromite was discovered in Lancaster county, Pa., and the control of this property was also obtained by Mr. Tyson. It was afterwards developed into the famous Wood mine, which has produced about 95,000 tons of chromite. Chromite mining in Maryland and Pennsylvania continued for a great many years until many of the deposits or pockets of chromite were worked out. About the time the ore began to grow scarce in these states, it was discovered in California, and for a few years a number of thousands of tons were shipped to Baltimore. When, however, the importation of chrome ore began, about 1884, the chrome mining industry in the United States began to decline. There are known deposits of this mineral in quantity in California and North Carolina, and probably deposits exist in Pennsylvania and Maryland; but, on account of the low price at which the foreign ore can be landed at Baltimore, but a small portion of that used in the United States is mined here. New uses for chromium and the construction of railroads through some of the chrome fields will

[1] The Mineral Industry, Vol. II, page 151.

[2] Transactions of the American Institute of Mining Engineers, Vol. XXV, page 487.

undoubtedly cause an increase in this industry during the next few years.

The uses of chromite, at present the only source of chromium, can be readily divided into three heads:

1. As a mineral: In the manufacture of bricks as hearth linings for basic, open-hearth furnaces, and for water-jacket furnaces in copper smelting. For these purposes ores carrying as low as 40 per cent of chromic oxide can be used. It is also probable that chromite can be used to advantage in other furnaces, especially where it is desirable to use fluorspar as a flux.

2. In chromium alloys: Chromite is used to a considerable extent in the preparation of a ferro-chromium alloy. The preparation of this alloy, which is used in the manufacture of armor plates and armor-plate-piercing projectiles, has become a very important industry. The ferro-nickel alloy is also used in the manufacture of armor plate. It is generally made by the addition of these two alloys of iron to molten steel before it is cast into the ingot; they produce a more or less homogeneous triple alloy.

3. In chromium salts: The first use of chromite was in the preparation of the salts, chromate and bichromate of potash, used in dyeing, tanning, and in the manufacture of pigments; this continues to be its chief use. It was about 1800 that the value of these salts as pigments was discovered, but it was not until the discovery of deposits of chromite that they were used commercially. Some chromium salts are also used for medicinal purposes.

NICKEL AND COBALT.

Nickel and cobalt mining in the United States began probably in 1863 with the opening of the Gap mine, in Lancaster county, Pa. This mine was worked almost continuously and very extensively from 1863 until 1880, and was the only nickel mine then worked on the American continent. With the discovery, however, of the nickel deposits in the Sudbury district, Ontario, Canada, and the moderate prices which prevailed for nickel, work at this Gap mine began to decrease, and about 1891 ceased altogether. It is very probable that there are still good deposits of nickel ore in quantity in this mine and that in the near future it will again become a producer. Since 1891 most of the nickel and cobalt produced in the United States has been at Mine Lamotte, Mo., where it has been obtained as a by-product in lead mining. Attempts were made to mine nickel in North Carolina about 1890, and although the mineral genthite, a nickel silicate, was found in some quantity at a number of places, there was only one place—near Webster, Jackson county—that gave any indication whatever of containing it in commercial quantity. Considerable work was done, but in 1891 the mine was closed and remained so until 1902, when the shafts and drifts were reopened and several carloads of ore were shipped for experimental purposes. There has also been some development of nickel deposits in Oregon and Idaho, and a few tons of ore have been shipped for experimental purposes, but none of the mines can be called producers.

The first general use of nickel commercially was probably in the manufacture of German silver or albata, an alloy of zinc, copper, and nickel. Articles made of iron and plated with nickel have to some extent replaced those made of German silver. Another of the earlier uses of nickel was for coinage, which is yet carried on quite extensively by the United States and many of the European countries. With the introduction of nickel in the manufacture of a special steel the demand for it has largely increased, so that this use of the metal has become the most important. Large quantities of nickel steel are used in the manufacture of armor plates, turrets, propeller shafts, crank shafts, etc. Another use that has received favorable consideration is in the manufacture of nickel-steel rails, which were first used by the Pennsylvania Railroad Company, and evidently gave entire satisfaction.

Cobalt is put on the market as the oxide and used almost entirely for coloring glass, porcelain, and similar substances.

TUNGSTEN AND MOLYBDENUM.

The mining of tungsten and molybdenum ores in the United States has become an established industry within the past few years only. Tungsten ores were mined in Colorado and Connecticut, and molybdenum ores in Washington.

Until lately the uses of these metals were few, requiring a comparatively small amount of their salts to satisfy the demand. The salts of tungsten were used as a mordant in dyeing and printing and as fireproof material for wearing apparel, while the principal use of molybdenum was in the manufacture of ammonium molybdate, used by chemists in the determination of phosphoric acid. A small amount of molybdenum salts is used in the preparation of blue carmine or molybdenum blue in the coloring of porcelain. The use, however, of these two metals in the preparation of ferro alloys has led to an increased demand, especially for tungsten, which, when added to steel, increases its hardness and toughness, and is believed by some to make it superior for certain purposes to any other manufactured. Tungsten steel is also used in the manufacture of tool steel, spring steel, and sounding plates and wires for pianos, where hardness and strength are especially desired. Molybdenum steel, the beneficial properties of which are similar to those of tungsten, is beginning to be used, but in much smaller quantity.

RUTILE.

The only titanium mineral mined for commercial purposes is rutile, a titanium oxide. Titanium was formerly considered one of the very rare metals, but it has

now been proved to be one of the commoner elements and is very widely distributed. In the future, besides rutile, the chief commercial source of titanium will be the mineral menaccanite (ilmenite), a titanium iron oxide. Rutile has been produced at Roseland, Nelson county, Va., and in Chester county, Pa. Only a small quantity is required to satisfy the demand, and the product does not amount to much over 100 tons of the crude ore per year.

The uses of rutile are principally in the ceramic industry for coloring porcelain and in the manufacture of artificial teeth. The titanium oxide will, under favorable conditions, impart a fine yellow color to the porcelain, and it is also capable of being used with other substances to produce secondary colors. The amount of titanium oxide used in the manufacture of artificial teeth is from five-tenths of 1 per cent to 2 per cent of the total materials used in making them.

At the present time no titanium is used commercially, as far as known, in the manufacture of titanium steel, although irons have been made containing a considerable percentage of titanium, the result of using ores for their iron contents rather than their titanium. Considerable work has been done, however, experimentally in regard to the use and value of titanium steel and with a great deal of success. It is probable that the introduction of this kind of steel into the general market is not far distant. Its properties of special interest are elasticity, and greater elongation and ductility than ordinary carbon steel.

URANIUM AND VANADIUM.

The production of uranium and vanadium ores during 1902 was all in Colorado. They have been mined in small quantities for a great many years, some of the salts of uranium being used to produce a pure black glaze on porcelain, while other salts are used in the decoration of glass and china ware, giving permanent colors. Vanadium salts are used in the coloring of glass, but principally in the preparation of vanadic acid, as a mordant, for aniline black in dyeing. The use of uranium and vanadium in the manufacture of special steels is still in the experimental stage, but enough has been done to prove that they increase tensile strength.

ASBESTOS

ASBESTOS.

By Joseph Hyde Pratt.

Two distinct minerals are included in these statistics as asbestos, one being a variety of amphibole and the other the fibrous variety of serpentine known as chrysotile. It is the latter that is the more valuable and for which there is the greater demand. In the United States, however, it is, thus far, principally the amphibole variety that has been mined. The low value of this mineral and the uncertain demand have caused a wide variation in production. The first census statistics for asbestos were reported in 1880, when, among minor minerals in the Report on Mining Industries, 7 mines were shown to have been operated—4 in Maryland and 1 each in Georgia, New York, and South Carolina. The number of employees reported was 17, who received $1,400 in wages. There was no cost of supplies or materials given. The production of asbestos was 150 tons, valued at $4,312. The company operating in Georgia was incorporated with a capital of $10,000.

At the Eleventh Census there was no record of the number of mines or establishments. The capital represented was stated to be $42,600; the employees, including foremen and office force, were 12; and the wages paid, not including office force, but including $1,900 for development work in Wyoming, were $2,700. The cost of supplies was $525. The production for that year (which was entirely from California) was only 30 tons, valued at $1,800.

Because of the lack of uniformity of the statistics of these two years, they can neither be compared with each other nor with those for 1902, except as regards the quantity and value of the production.

Table 1 is a summary of the statistics for 1902.

Table 1.—*Summary: 1902.*

Number of mines or quarries	4
Number of operators	4
Salaried officials, clerks, etc.:	
Number	7
Salaries	$2,628
Wage-earners:	
Average number	23
Wages	$8,250
Miscellaneous expenses	$1,758
Cost of supplies and materials	$8,233
Product:[1]	
Quantity, short tons	2,505
Value	$46,200

[1] The United States Geological Survey reports 1,005 short tons, valued at $16,200, which is the product marketed. Census figures represent the product mined.

Detailed statistics of this industry can not be published by states without disclosing the business of individual establishments, for, of the 4 mines or quarries reported, 1 each was located in Connecticut, Georgia, Massachusetts, and Virginia. Fifteen properties that were developed or prospected for asbestos in former years were idle in 1902. Three each of these were situated in Georgia, North Carolina, and Vermont, 2 in California, and 1 each in Pennsylvania, Virginia, Wisconsin, and Wyoming. Among the owners were 4 incorporated companies, with an authorized capital of $2,500,000, of which $1,655,070, all common, had been issued. Many of these properties, as those in North Carolina, Vermont, and Wyoming, contain the chrysotile variety, and it had been expected that some of these, especially those in Vermont, would report a marketable production for 1902.

Capital stock of incorporated companies.—Of the 4 operators in the asbestos industry, 3 were incorporated companies, 1 each of these being located in Connecticut, Georgia, and Virginia. In Table 2 are shown the details of their capital stock.

Table 2.—*Capitalization of incorporated companies: 1902.*

Number of incorporated companies	3
Capital stock issued	$2,010,000
Total authorized—	
Number of shares	1,400,000
Par value	$2,300,000
Total issued—	
Number of shares	1,110,000
Par value	$2,010,000
Common—	
Authorized—	
Number of shares	1,100,000
Par value	$2,000,000
Issued—	
Number of shares	975,000
Par value	$1,875,000
Preferred—	
Authorized—	
Number of shares	300,000
Par value	$300,000
Issued—	
Number of shares	135,000
Par value	$135,000

None of the companies showed bonded indebtedness and none reported dividends. Of the authorized capital stock, 87.4 per cent of the total value had been issued, of which 6.7 per cent was preferred stock. The capital reported for this industry is extremely large when compared with the value of the production for 1902 and with the production for any of the past years since

the industry was started. This is due to the fact that most of the companies sending their statistics for 1902 were organized during the past few years, when the methods of incorporation in vogue have been for highly capitalized companies, regardless of the real value of the property or plant or of the magnitude of the business that could be built up. The companies have been organized supposedly with the idea that the amphibole asbestos can be mined and manufactured and used for the same purposes as the chrysotile asbestos. Were this the case the capitalization would not be so much out of proportion to the value of the properties as it is. The capitalization given in the above statistics does not refer to asbestos companies manufacturing products from chrysotile asbestos imported from Canada, but to those mining asbestos in this country and manufacturing products directly from it.

Employees and wages.—Of the total amount, $10,878, reported as paid for salaries and wages, $8,250, or 75.8 per cent, was paid to the wage-earners, and $2,628, or 24.2 per cent, to the salaried employees. There were 5.8 wage-earners, on the average, to a mine. The average number of wage-earners, as may be seen by reference to Table 6, was greatest (61) during October and least (7) in June. The dull months were from January to July, both inclusive. Table 6 also shows the average number of wage-earners at each specified daily rate of pay. Of the 23 employees, 17 were classed as miners or quarrymen. Of these, 13 received from $1 to $1.24 per day; 1 received from $1.25 to $1.49 per day; and 3 received from $1.50 to $1.74 per day. There were 2 machinists or blacksmiths, 1 of whom received the highest rate paid, which was from $2.50 to $2.74 per day. There were 2 firemen, each of whom received from $1 to $1.24 per day. One other wage-earner, who did miscellaneous work, received from $1.50 to $1.74 per day. The prevailing rate of pay was from $1 to $1.24, 16 having received this rate. These comparatively low rates of pay are due to the fact that most of the miners were employed in the South, where the rates of pay are much lower than either in the North or the West.

Supplies, materials, and miscellaneous expenses.—The principal item of expense, next to that for wages, was for supplies and materials, for which $8,233 was reported as having been expended. The miscellaneous expenses of $1,758 were incurred for rent of office, taxes, insurance, and other sundries. Thus, the total cost, including wages, salaries, supplies, materials, and miscellaneous expenses, was $20,869.

Mechanical power.—Steam engines with a total of 105 horsepower were used in producing the asbestos, this power being reported by 2 establishments—1 in Georgia and 1 in Virginia.

Production.—The total production of asbestos in the United States for 1902 was 2,505 short tons, valued at $46,200. This production of asbestos is the largest reported during the period beginning with 1880, in which year the statistics for this mineral were first obtained. Of this production, however, 1,500 tons represents the rock just as mined. The statistics do not, therefore, represent the total value of the asbestos as it is put upon the market. In some instances the asbestos was crushed, separated, and otherwise prepared at the mines. As in such cases the mining and the processes to which the mineral is subjected were conducted under the same management and with the same capital, it is impracticable to separate the statistics. The United States Geological Survey has published annual statistics of the quantity and value of asbestos, and these are shown in Table 3, for the years from 1889 to 1902, inclusive.

TABLE 3.—*Production of asbestos: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

YEAR.	Quantity (short tons).	Value.	Average value per ton.
1889	30	$1,800	$60.00
1890	71	4,560	64.23
1891	66	3,960	60.00
1892	104	6,416	61.69
1893	50	2,500	50.00
1894	325	4,463	13.73
1895	795	13,525	17.01
1896	504	6,100	12.10
1897	580	6,450	11.12
1898	605	10,300	17.02
1899	681	11,740	17.24
1900	1,054	16,310	15.47
1901	747	13,498	18.07
1902	1,005	16,200	16.12

As is seen from the above table, there has been a very wide variation in the quantity reported from year to year, and also in the value. This is due, as stated above, to the uncertainty of the demand for this variety of asbestos. The highest prices were received for asbestos during the years from 1889 to 1893, when the values varied from $50 to $64.23 per ton. These high prices were undoubtedly due to the fact that certain manufacturers required only a few tons of asbestos, and in order to obtain these small quantities they were obliged to pay this increase in price. The total quantity of asbestos produced in the United States since 1880 amounts to only 10,917 tons, which would make an average production of 474 tons per year. The greatest quantity produced in one year was 1,200 tons in 1882, and the next greatest, 1,054 tons, in 1900. The average value varied from $64.23 in 1890 to $11.12 in 1897. In 1894 there was a decided drop in the value of amphibole asbestos, from $50 to $13.73, and since that time the average has not exceeded $18.07. In 1902 the values varied from $16 to $40 per ton, the latter price having been received for 5 tons of chrysotile asbestos which were obtained as a by-product in talc mining.

The detailed statistics of the asbestos industry for 1902 are shown in Table 6.

The quantity of the amphibole asbestos produced in the United States during 1902, and considered as used, was 2,500 tons, valued at $46,000, while the amount of chrysotile asbestos was valued at $762,632, of which only a quantity valued at $200 was produced in this country, the balance having been practically all imported from Canada. The imports, as published by the United States Geological Survey, are given in Table 4 for the years 1889 to 1902, inclusive.

TABLE 4.—*Value of asbestos imported: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

YEAR ENDING DECEMBER 31—	Unmanufactured.	Manufactured.	Total.
1889	$254,239	$9,154	$263,393
1890	252,557	5,342	257,899
1891	353,589	4,872	358,461
1892	262,433	7,209	269,642
1893	175,602	9,403	185,005
1894	240,029	15,989	256,018
1895	225,147	19,731	244,878
1896	229,084	5,773	234,857
1897	263,640	4,624	268,264
1898	287,636	12,897	300,533
1899	303,119	8,949	312,068
1900	331,796	24,155	355,951
1901	667,087	24,741	691,828
1902	729,421	33,011	762,432

Table 5 shows the production of asbestos from 1889 to 1902 in Canada, from which nearly all of the mineral used in the United States is obtained.

TABLE 5.—*Annual production of asbestos in Canada: 1889 to 1902.*

1902	[2]40,416	1,148,319

[1] Including asbestic. [2] Including 10,197 tons of asbestic.

DESCRIPTIVE.

As is seen from the preceding tables and text, the asbestos mining industry in the United States is very small, and there is but little chance of its increasing, unless large deposits of the chrysotile asbestos are discovered and developed. There are very large deposits of amphibole asbestos, but, as already stated, there is not sufficient demand for this variety to create a large industry.

Although in many respects the two varieties are similar in physical properties, there is a wide variation in strength of fiber, the chrysotile variety being superior in both strength and elasticity to any amphibole asbestos, and for this reason capable of being used for many purposes for which the latter can not be adapted. With respect to their heat-resisting properties, they are about equal, so that when asbestos is to be used as an ingredient in fireproof paint, wall plaster, as boiler coverings, as packing, in the manufacture of fireproof safes, and for nearly all purposes in which nonconductivity of heat and not strength of fiber is the important factor, the amphibole variety can be used to as good advantage as the chrysotile. For these purposes there is probably but little chrysotile asbestos used, except what is known as asbestic or the waste portions. There are, however, a number of other minerals, such as infusorial earth, tripoli, talc, and mica, that are strong competitors of the amphibole asbestos.

On the other hand, where strength of fiber is essential as well as nonconductivity of heat, as in the manufacture of cloth, rope, felt boards, tubes, washers, and blocks of various shapes, it is only the chrysotile variety that can be used. The fibers of chrysotile are seldom over 2½ inches long, and are usually from one-half to 1½ inches in length. The fibers of the amphibole variety, however, occur up to 3 feet in length, and when this asbestos is fairly free from grit, it appears like a very attractive proposition. In a number of cases deposits of amphibole asbestos have been developed in attempts to compete with chrysotile, but in each case the effort has resulted in failure.

It is interesting to note the variation in the value of these two varieties of asbestos; for the amphibole variety there is usually simply the one flat rate, which has varied, since 1894, from $11.12 to $18.07 per ton. On the other hand, the chrysotile asbestos varies in price according to the different grades as follows:

	Per ton.
No. 1 asbestos	$150 to $250
No. 2 (white) asbestos	75 to 125
No. 3 (red) asbestos	50 to 75
Mill fiber, or paper stock	20 to 40
Asbestic	1 to 3

The mill fiber, or paper stock, is the minute fibers of asbestos which have become broken and are not capable of being used for weaving, and the asbestic is the final waste material, which contains a small amount of minute fibers and a considerable amount of the crushed serpentine rock.

Occurrence.—Since 1880 asbestos properties have been prospected and developed in the United States in Arizona, California, Georgia, Maryland, Massachusetts, Michigan, New Jersey, New York, Pennsylvania, South Carolina, Vermont, Virginia, and Wisconsin. Although a considerable search has been made for asbestos deposits in this country, it has resulted thus far only in the discovery of producing deposits of the amphibole variety.

At the present time the deposits of amphibole asbestos that are being worked or developed to any extent are as follows:

About 3 miles from the railroad station at New Hartford, Conn., a deposit of this asbestos occurs in a

ledge that outcrops strongly for a distance of about 750 feet in length, with a width of 20 feet. It has been opened in a number of places to a depth of 45 feet. A plant for crushing and preparing this material for the market was being erected in 1902.

At Sal mountain, 12 miles northwest of Clarksville, Ga., are located the largest developed asbestos deposits in the United States.

In the northeast corner of Rabun county, Ga., and about 1½ miles from Russell, S. C., deposits of amphibole asbestos occur.

In Virginia, about 14 miles south of Bedford City, a deposit of amphibole asbestos occurs in seams and veins varying from 8 to 50 inches in thickness.

In Wisconsin, near Stevens Point, Wood county, a deposit of this asbestos has been developed, although no asbestos was produced during 1902.

Many other deposits of amphibole asbestos are known to exist in the United States, but unless they are very favorably located for mining, and have good transportation facilities, it is practically impossible to work them on a profitable basis.

Chrysotile asbestos has been found sparingly associated with many of the outcrops of basic magnesian rocks that extend northeasterly from Alabama across Georgia, South Carolina, North Carolina, Virginia, Maryland, Pennsylvania, the New England states, and into Canada. These rocks are more or less altered to secondary serpentine, and in the more northern sections different areas are often completely converted to this secondary rock, as those of Pennsylvania, Maryland, Vermont, and Quebec province in Canada, while in North Carolina, Georgia, and Alabama there are but very few areas that have been altered to this extent. As would be expected, it is only in those areas in which the rocks have been completely changed to serpentine that the chrysotile asbestos occurs in commercial quantity. Although only the very small amount of this variety of asbestos obtained from Massachusetts was produced from a mine already in operation, yet a great deal of work was done on deposits of this variety in Vermont and Wyoming, with a smaller amount of work on deposits in California, Michigan, and North Carolina.

The Vermont deposits are located in the north central part of the state, in the town of Eden, Lamoille county, and in the adjacent town of Lowell, Orleans county.

The Wyoming deposits, which are located in the vicinity of Casper, Natrona county, have been pretty thoroughly developed, but thus far operations have not been sufficiently advanced for the marketing of the product.

The deposits of California thus far developed are in Riverside county. The other deposits in this state and those in North Carolina, have been developed little more than to prove that the chrysotile asbestos is to be found.

The basic magnesian rocks of the Pacific slope, in California, Oregon, and Washington, have in many instances been entirely converted to secondary serpentine, and are promising fields for investigation. It is possible that when they are thoroughly prospected they will be found to contain deposits of the chrysotile asbestos capable of profitable operation.

ASPHALTUM AND BITUMINOUS ROCK

ASPHALTUM AND BITUMINOUS ROCK.

By Joseph Struthers, Ph. D.

Asphaltum became known to Census statistics in 1860, when it was reported from California among manufacturing statistics as "asphaltum work." At the census of 1870 no report was published from California, but an establishment in West Virginia was recorded in the statistics of mining as having produced asphaltum valued at $450,000. At the census of 1880 West Virginia dropped out and California returned statistics for two mines, being shown among mining industries. At the Eleventh Census, the inquiries for which, as to mining, covered the year 1889, asphaltum was shown among mineral industries in California, Kentucky, and Utah.

At the census of 1902 Arkansas, Indian Territory, and Texas were added to these, making 5 states and 1 territory reporting asphaltum. The asphaltum by-product of petroleum refineries, being the result of manufacturing processes, was included among manufactures at the census of 1900, with a number of other by-products, under the caption of "Residuum" in the Report on Petroleum Refining. This product is not, therefore, included in the statistics for 1902 herewith presented, which concern the mining of the various kinds of hydrocarbon rocks having an asphaltic base, namely, bituminous limestone and sandstone, and some of the purer forms of bitumen, as elaterite, gilsonite, and uintaite.

The comparative statistics from 1860 to 1902 are presented in the following table:

Table 1.—*Comparative summary: 1860 to 1902.*

	1902	1889	1880	1870	1860

Quantity, short tons	66,238	51,735	444	30,000	(1)
Value	$236,728	$171,537	$4,440	$450,000	$10,000

[1] Not reported. [2] Not reported separately.
[3] The United States Geological Survey reports 105,458 short tons, valued at $765,048, which includes the residual asphaltum product of petroleum refineries. This residuum being the product of manufacturing processes is not reported by the Census.

From 1860 to 1889 the production was quite irregular. The large increase in value of product from $10,000 in 1860 to $450,000 in 1870 was due to the discovery in West Virginia of a vein of grahamite, which was soon exhausted. A revival of the industry took place between 1880 and 1889. The increase in wages from 1889 to 1902 was $16,067, or 25.3 per cent, and the increase in value of product was $65,191, or 38 per cent. The 24 mines reported for the industry in 1902 were controlled by 19 incorporated companies, 3 individual proprietors, and 2 firms.

The state showing the largest production was California, with 35,377 tons, or 53.4 per cent of the total, and a value of $101,353, or 42.8 per cent of the whole.

30223—04——62

Kentucky was second with 22,498 tons, or 34 per cent, and $68,704, or 29 per cent of the value. Indian Territory was third with 2,566 tons, or 3.9 per cent, and $11,754, or 5 per cent of the value. The remainder, 5,797 tons, or 8.7 per cent, and $54,917, or 23.2 per cent of the value, was for all other states, of which Utah was the largest producer, both in quantity and value.

Thirteen mines were idle—3 in California, 2 in Indian Territory, 2 each in Missouri, Texas, and Utah, and 1 each in Kentucky and Tennessee. There were 6 mines for which development work was reported but no production—3 in California, and 1 each in Arkansas, Colorado, and Indian Territory. The statistics for these are shown in the following statement:

Development work: 1902.

Number of mines or quarries	6
Number of operators	6
Salaried officials, clerks, etc.:	
Number	5
Salaries	$3,160
Wage-earners:	
Average number	2
Wages	$1,030
Miscellaneous expenses	$1,602
Cost of supplies and materials	$72

Capital stock of incorporated companies.—The capitalization of 17 of the 19 incorporated companies, 2 failing to report in this particular, is shown in the following table:

Number	128	.....	.....	128	.....
Par value	$110,000	.....	.....	$110,000	.....

[1] Includes 1 company in Texas, and 1 in Utah.

The capital stock of the 5 Kentucky companies constituted 54.7 per cent of the total. The par value of the capital stock issued by the 17 companies reporting was 92.3 per cent of the total amount authorized. No bonds were issued and the par value of those authorized amounted to only $110,000, all in Kentucky.

The production of the active mines operated by the 19 incorporated companies, including the 2 companies not reporting their capital, was 59,448 tons, or 89.7 per cent of the total, and $201,346, or 85 per cent of the total value.

Employees and wages.—The wage-earners constituted 75 per cent of the salaried employees and wage-earners, and their wages were 62.3 per cent of the total salaries and wages. Kentucky led, with 41.7 per cent of the wage-earners and 28.4 per cent of the wages, California being second, with 20.5 per cent and 25.2 per cent, respectively. In addition to the amount paid in wages, $10,060 was paid to 60 employees for contract work.

As shown in Table 5, November was the month during which the largest number of wage-earners was employed in the industry, although employment was not very variable during the year. In Indian Territory the largest number is shown for December. The smallest number of wage-earners for all the states appears for June. Of the total number of wage-earners, 58, or 37.2 per cent, received from $1 to $1.24 per day, and 27, or 17.3 per cent, from $2.50 to $2.74 per day. Machinists, blacksmiths, carpenters, and other mechanics received the highest rate—from $4 to $4.24. Of the total wage-earners, 116, or 74.3 per cent, were miners or quarrymen. Fifty, or 43.1 per cent of these, received from $1 to $1.24 per day; 25, or 21.6 per cent, from $2.50 to $2.74; and 14, or 12.1 per cent, from $2.75 to $2.99. The 21 "all other wage-earners" were engaged in miscellaneous work about the mines and quarries.

Supplies, materials, and miscellaneous expenses.—The cost of supplies and materials, reported as $21,928, is the largest item of expense other than wages and salaries. Of the $19,753 expended for miscellaneous expenses, $16,897, or 85.5 per cent, was paid for rent of offices, taxes, insurance, interest, and other sundries, and $2,856, or 14.5 per cent, for royalties, and rent of mine and mining plant.

Mechanical power.—Of the 24 operators from whom reports were received, 8 reported the use of power, the total of the primary power being 720 horsepower. Of this, 660 horsepower, or 91.7 per cent, was steam, and 60, or 8.3 per cent, gas or gasoline. There was, in addition, 1 electric motor having 25 horsepower. Kentucky reported 53.8 per cent of the steam power, and

Indian Territory 46.2 per cent of the steam and all of the electric power. The total gas or gasoline power was reported from California.

Production.—The United States Geological Survey has published annual statistics of the production of asphaltum since 1882, but these are not comparable with Census statistics, for the reason that after the year 1891 they include maltha, or brea, and the asphaltum by-products of petroleum refineries. During 1902 the quantity of by-product asphaltum produced by oil refineries in California and Texas, and sold and used in the trade as asphaltum, amounted to 20,826 short tons, valued at $303,249.[1]

According to the reports received for 1902, the average price of asphaltum was $3.57 per ton. The range was from $1.50 to $50, the former for less than 100 tons mined in Indian Territory, and shipped in the crude state, and the latter for less than 1,000 tons of elaterite mastic mined in Utah, f. o. b. at the mines.

Most of the imported asphaltum comes from the Island of Trinidad, British West Indies. The following table, compiled from tables published by the United States Geological Survey, shows the total imports into the United States from all countries since 1889. The values are at point of shipment:

[1] United States Geological Survey, "Mineral Resources of the United States," 1902.

TABLE 3.—*Crude asphaltum imported for immediate consumption: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

YEAR ENDING DECEMBER 31—	QUANTITIES. From Trinidad. Total (long tons).	Land (long tons).	Lake (long tons).	From all countries (long tons).	Total value.
1889	58,978	13,568	45,410	61,952	$138,163
1890	57,324	17,417	39,907	73,861	223,368

[1] In addition to the crude asphaltum imported in 1895, there was some manufactured or refined gum asphaltum, valued at $36,664. In 1896 the value of the manufactured asphaltum imported was $77,449, and in 1897, $25,095. The quantity was not reported.
[2] Includes 3,069 long tons, "dried or advanced," valued at $17,005.
[3] Includes 4,264 long tons, "dried or advanced," valued at $35,395.
[4] Includes 5,141 long tons, "dried or advanced," valued at $49,242.
[5] Includes 6,754 long tons, "dried or advanced," valued at $36,958.
[6] Includes 7,239 long tons, "dried or advanced," valued at $62,561.

Exports of crude asphaltum during 1902 amounted to 2,930 long tons, valued at $23,564.

The production of asphaltum and asphaltic rock in the principal producing countries of the world, from 1890 to 1901, inclusive, is given in Table 4.

TABLE 4.—PRODUCTION OF ASPHALTUM IN PRINCIPAL PRODUCING COUNTRIES: 1890 TO 1901.

[1] Statistics not yet available.

The detailed statistics of the industry in the United States for 1902 are shown in Table 5.

DESCRIPTIVE.

Asphaltum is the name applied to different forms of bitumen. Its composition varies, and it is known by many other names, bestowed on account of some special characteristic resulting from its composition or the locality from whence it has been obtained. The most common of these names are: Natural mineral pitch, Jews' pitch, Trinidad asphalt, Cuban asphalt, Dead sea bitumen, manjak, maltha, brea, chapapote, elaterite, wurtzilite, nigrite, gilsonite, grahamite, and uintaite.

Asphaltum has been an article of commerce from remote antiquity, the supply having been obtained from the deposits near the Dead Sea, where the material floated on the surface or was washed ashore by the waves, the product being known to the Arabs by the name of Hajar Mousa, or Moses's stone.

In Germany asphaltum was known as early as 1626 under the name of "harzerde" (pitch earth), which was described in 1692 by Doctor Amiest as asphaltum.

Bituminous limestone is mentioned by Doctor Erynis in several publications prior to 1721. The deposits at Seyssel, France, were discovered in 1802, and the asphaltum interests of France and Switzerland were united in 1832 by Count de Sassenay.

Physical and chemical characteristics.—Asphaltum ranges in form from the liquid maltha to the hard, solid glance pitch, which gradually merges into asphaltic coal. The specific gravity of pure asphaltum ranges from 1 to 1.3, and the hardness from 2 to 3. The solid varieties have a black or dark-brown color and a peculiar characteristic pitchy odor when rubbed.

Asphaltum breaks with a more or less splintery fracture and does not soil the fingers. It is very brittle at low temperatures, but upon being warmed, although it remains sufficiently hard to be broken by a sharp blow, at the same time it yields to a steady pressure or tread. Asphaltums differ much in their properties, and all do not possess the binding power so necessary for a lasting pavement; they shade by insensible gradations into brittle asphaltic coals. The melting point of asphaltum is usually low. It is very inflammable, burns with a yellow, smoky flame, and when pure leaves very little if any residue. It is insoluble in water, slightly soluble in alcohol and fixed and essential oils, and readily soluble for the greater part in ether, oil of turpentine, naphtha, and carbon bisulphide. With benzole it forms a solution of an intense black color, used as a varnish. When subjected to destructive distillation, asphaltum is decomposed into a distillate of oils and a tarry residue which becomes solid when cold.

The chemical composition of asphaltum is so complex that elementary analyses throw little light on the subject. It still remains an open question whether important groups of definite and characteristic hydrocarbons can be separated and recognized.

Many chemical analyses of asphaltum from various localities have been published from time to time which, however, are of scientific value only. Of these analyses the following are characteristic:

Analyses of pure asphaltum, exclusive of earthy matter and other mechanical impurities.

CHEMIST.	Place.	Total per cent.	PER CENT OF—				
			Carbon.	Oxygen.	Hydrogen.	Nitrogen.	Sulphur.
Bowen	Trinidad	100.00	85.89	0.56	11.06	.....	2.49
Regault	Mexico	100.00	80.34	10.09	9.57	.....	.....
Bossingault	Peru	100.00	88.67	1.65	9.68	.....	.....
Bossingault	Cuba	100.00	81.50	6.90	9.60	.....	.....
Bossingault	Colombia	100.00	88.31	1.68	9.64	0.37	.....
Kayser	Palestine	100.00	80.00	0.40	9.00	10.00	0.60

Means other than chemical analysis are generally used to ascertain the commercial value of asphaltum. The first of these is a solubility test of the sample dried at 212° F. in various solvents, as carbon bisulphide, alcohol, turpentine, ether, petroleum, naphtha, etc. Distillation is often used and the losses at various temperatures are recorded. The quantity and quality of mechanical impurities (water, clay, earthy matter) contained in the sample are also determined; finally, the best test of its applicability for pavement purposes is its viscosity at various temperatures. In some cases the value of an asphaltum for use in pavement construction is determined by an actual trial.

The substances classed as bitumens are hydrocarbon compounds, the more important of which, arranged in the order of their specific gravities at 70° F., are divided into six groups:

1. Natural gas.
2. Natural naphtha.
3. Petroleum, or natural oil.
4. Maltha, or soft, sticky bitumen.
5. Asphaltum, or stiff, sticky bitumen.
6. Glance pitch, or dry, brittle bitumen (often called gilsonite).

In addition to the substances comprising the above list, there are other bitumens of chemical interest only, which possess no commercial value.

In commerce there are four chief classes into which asphaltum is divided: (1) The natural liquid form, called liquid asphaltum or maltha; (2) asphaltum mixed with more or less vegetable and earthy matter, which yields, by the removal of the mechanically contained impurities, the product called hard, refined, or gum asphaltum; (3) asphaltum contained in sand or sandstone, called bituminous sandstone; (4) asphaltum contained in limestone, called bituminous limestone.

In addition to the natural products given in the above list mention should be made of "by-product asphaltum," which is obtained in the refining of crude petroleum having an asphaltic base to yield commercial illuminating and lubricating oils. There is no strict line of demarcation between oils classed as petroleum oils and those considered as asphaltum oils.

The term bituminous rock is applied to both sandstones and limestones impregnated with asphaltum. Bituminous rock is sold and shipped without previous refining, and is consumed chiefly for street pavements, being generally mixed with other ingredients at the place of use. An inconsiderable proportion, however, is treated for its asphaltic content, the product being sold as refined or gum asphaltum.

Asphaltic or bituminous limestone is a natural compound of asphaltum and limestone, at times containing,

in addition, other bituminous substances, sand, and sulphur-bearing compounds. The quantity of asphaltum present varies in different deposits, and even in different portions of the same deposit, up to 20 per cent. The grain of asphaltic limestone is extremely fine, and under the microscope each grain appears completely coated with asphaltum. It is this property which renders the natural product of greater value than an artificial mixture of asphaltum, fine sand, and pulverized limestone.

Analyses of representative asphaltic limestones, showing their general composition, are given below.

Analyses of representative asphaltic limestones, showing their general composition.

CHEMIST.	Place.	Total per cent.	PER CENT OF—

[1] Includes clay and iron oxide and magnesium carbonate.

The formation of natural asphaltum is attributed by some geologists to the slow decay and decomposition of vegetable matter whereby the contained hydrocarbons have been distilled and subsequently condensed in the adjoining rocks, the product thus collected forming asphaltum deposits. The formation of artificial asphaltum in the manufacture of gas by the distillation of coal in a retort is quoted as a proof of this theory. In this process a considerable portion of tarry matter passes over and is collected during the distillation which yields, by a second distillation, naphtha and other volatile products, leaving as a residue in the retort a tarry substance possessing the properties of asphalt.

Other geologists claim that asphaltum is the result of the decomposition of certain petroleums under the influence of heat, accompanied by polymeric changes not fully understood, whereby the more volatile constituents of the oil are expelled, leaving the residue in the form of solid asphaltum.

Occurrence.—Asphaltum is seldom found native or pure, the principal known deposits containing it in admixture with other materials, chiefly earthy matter, sand, or sandstone and limestone. It occurs disseminated throughout many crystalline rocks, and is not restricted to any one geologic formation. It is not known, however, in the Archæan age. In many cases it has been deprived of volatile matter, which has caused it to resemble anthracite. It occurs also in veins that have been evidently injected into fissures, while in a plastic condition, exemplified by the minerals albertite and grahamite. It exists as a liquid in bituminous limestones and sandstones, from which it oozes, constituting the so-called "tar springs."

The most important of the liquid asphalt deposits are found in southern California, of which the Las Conchas mine on the ocean near Carpentaria has been operated successfully. The maltha impregnates a clean Quaternary beach sand of from 20 to 30 feet in thickness, overlying a bituminous shale, from which the liquid asphalt exudes. The crude sand containing about 20 per cent of bitumen is refined to a product of 95 per cent bitumen content. The refined liquid is used to soften solid asphaltum and to coat wood and masonry for protection against the penetration of moisture.

Asphaltum is found also in beds resulting from the oxidation either of mineral tar or, primarily, petroleum. This class includes the immense deposits at Tamaulipas and Moloacan, Mexico. There are many and diversified occurrences of asphaltum in Europe, the chief deposits being the bituminous limestones at Seyssel, France; at Val de Travers, in Neuchatel, Switzerland; in the Dinaric Alps, bordering the eastern coast of the Adriatic sea, and at Ragusa, Italy. In Asia it occurs at many localities in Syria, around the Dead sea, the source of the early supply of asphaltum.

The largest producing asphaltum deposit of the world is at Pitch Lake, on the island of Trinidad, where the asphaltum occurs in the form of a basin-shaped deposit 18 feet thick at the edges and 80 feet thick at the middle, with an estimated content of 6,000,000 tons of asphaltum. The deposit is supposed to be supported by water, and while solid enough to admit of the passage of wagon and horse, it has a slow movement which tends to draw in the tramway used to convey the excavated material to the shore of the lake, unless properly supported by branches of trees. In fact excavations of a depth of 20 feet have become filled in six months. The asphaltum is broken from the mass by means of picks, before daylight while the material is brittle; it is then loaded on cars and conveyed by the tramway to the shore, from whence it is carried to the pier, 3,500 feet distant, by an aerial wire-rope conveyor and dumped directly into the holds of the vessels. On the voyage it becomes agglomerated into a solid mass, which must be again broken up by pick in order to remove it from the vessel. The product is roughly refined by heating in tanks and straining the liquefied material through a screen for the separation of roots and other vegetable matter with which it is contaminated. There is a similar lake deposit near San Timolis, Venezuela, the product being known commercially as Bermudez asphaltum.

The principal deposits of natural asphaltum occur as shown in the following statement:

ASPHALTUM MIXED WITH EARTHY MATTER.	ASPHALTIC LIMESTONE.	ASPHALTIC SANDSTONE.

At the present time the chief producing localities are Trinidad, Dalmatia, Syria, Cuba, and the Seyssel, and Val de Travers deposits of bituminous limestones; local supplies of more or less value are obtained from other localities.

The following is a review by states of the asphalt industry in the United States during 1902:

Arkansas.—An asphaltum property near Pike City, Pike county, consists of a stratum of sand from 6 to 12 feet thick, containing various proportions of semi-fluid asphaltum. The product is obtained by sinking shallow pits, into which the material oozes from the bed. Borings have proved that the asphaltum beds extend over an area of several acres. A pit 100 feet in diameter has been dug, and a spur has been built to the railroad a half mile distant. A special feature of some portions of the bed is the occurrence of limestone with the sandstone, which yields a product available for paving purposes without the addition of other material.

The utilization of the asphaltum deposits in this state is solely a matter of cost of transportation. The average grade product should easily control the markets of Little Rock, Texarkana, and Fort Smith, and the higher grade material should compete advantageously with other asphaltum in cities as far distant as Memphis and St. Louis. It is also probable that pure asphaltum could be extracted from the asphaltic sandstone at a profit greater than that obtained by the sale of the crude product.

Analyses of samples of asphaltic rock from this district have been reported by Mr. C. W. Hayes,[1] as follows:

COMPONENTS.	Gray banded rock (per cent).	Brown cap sand (per cent).	Black sand rock (per cent).	Black gummy rock (per cent).	Calcareous sandstone (per cent).

Calcium carbonate	20.35	.....	.....	6.14	46.00

[1] Engineering and Mining Journal, December 13, 1902.

California.—On the Sisquoc ranch, Santa Barbara county, the principal asphaltum property is the mesa deposit, 1,300 by 5,000 feet in area and of a reported minimum depth of 125 feet, which is estimated to contain 25,000,000 tons of bituminous rock, equivalent to 5,000,000 tons of asphaltum. The rock is mined, elevated by an electric crane, and shipped in steel cars to the refinery works on the mountain side, where gravity is utilized to move the materials. The crude rock is crushed by steel rolls and heated in revolving steel-jacketed drums, and as it becomes softened by heat it is treated with gasoline until thoroughly saturated. It is then passed into a series of agitating drums, which separate the solution containing the asphaltum from the tailings; the solution flows by gravity to the stills, and the gasoline is removed and recovered for repeated use. The residue in the still, consisting of asphaltum of 99 per cent purity, is cooled and barreled for shipment.

The product of the companies operating these mines is chiefly a bituminous sandstone, largely utilized for paving purposes on the Pacific coast, where, owing to the simple method of its preparation and the cheap water freight rates, it competes successfully with other asphaltum paving mixtures. There is no production of asphaltic limestone in California worthy of mention. In addition to the producers of asphaltum from natural rock in this state, a large number of crude petroleum refineries have been established, which furnish a considerable quantity of by-product asphaltum obtained from the crude petroleum oils of California. By-product asphaltum possesses similar properties to that obtained from the rock deposits, and replaces it to a considerable extent in paving and other uses.

Indian Territory.—The known asphaltum deposits in this territory are almost entirely within the reservation of the Chickasaw nation. Development work has been started at Ravia, Dougherty, and Tar Springs, and at the two former localities soft asphaltic sands and a bituminous limestone have been mined, and at the last-named place asphaltic sandstone is produced. Grahamite is mined near Tar Springs, the product being hauled to Comanche, 18 miles distant, and then shipped by the Chicago, Rock Island and Pacific Railroad. Considerable prospecting by drills has been accomplished in the vicinity of Tar Springs, and other deposits of asphaltic sands have been found below the surface deposit, separated therefrom by beds of red and blue clay and shale. The thickness of the asphaltic sand beds varies from 3 to 20 feet, while the clay and the shale strata range from 5 to 40 feet in thickness. The lower limit of the asphaltic sand has been found at a depth of 600 feet from the surface. The present supply of asphaltum is obtained by open-cut working. The sandstone capping is removed by drilling and blasting, and the soft asphaltic sands are broken up by blasting and removed

by plows and scrapers to the refinery, where the sterile sand is segregated by mechanical concentration with hot water. The asphaltic material rises to the surface and passes to the reducers, where it is brought to the proper consistency by the application of heat and subsequently strained and barreled for shipment. The products vary with the demands of the market, and range from a semiliquid on the one hand to a hard and brittle form on the other. Very little of the latter is made, however, on account of the large amount of time and fuel required to produce it.

Kentucky.—The principal bituminous sandstone deposits in Kentucky are in Logan, Warren, Edmonson, Butler, Grayson, and Breckinridge counties, occupying an area of 20 by 50 miles in the central part of the state. The deposits are in fine-grained sandstone of the Subcarboniferous formation, and from geological evidence the asphaltum represents the residual matter from preexisting beds of petroleum. The numerous deposits in Grayson and Edmonson counties vary both in richness and magnitude, the range in the thickness of the beds being from 2 to 20 feet. But few of these deposits, however, are of commercial value. The richer deposits lie between strata of "black rock" from 1 to 2 feet thick, and the intervening asphaltum ledge varies in thickness from 3 to 15 feet and contains from 5 to 15 per cent of bituminous matter; below 4 per cent asphaltum content the material merges into "black rock."

Up to the present time only those deposits lying conveniently near railroad or river have been developed, and of such only those have been worked which offer the least difficulty in the way of uncovering. No tunneling or drifting has yet been attempted. At Bowling Green there is a 200-ton refining plant, equipped with corrugated rolls. The moisture in the material as it comes from the crushers is expelled by means of steam jets.

A property 4 miles northeast of Russellville, Logan county, has been developed quite extensively, the quarry face showing a 17-foot asphaltum ledge. The plant of this company includes a 250-ton gyratory crusher and plain 14 by 18 inch rolls. Quarries, mill, and tipple are connected by 1½ miles of narrow gauge track, and at the end of the year the rolling stock equipment consisted of 45 cars. At Louisville, the operating company has installed a plant for mixing and preparing asphaltum for street paving work, which has a daily capacity of preparing material to cover an area of 18,000 square feet.

An asphaltum company near Garfield, Breckinridge county, has a 100-ton plant. The asphaltic rock is broken in two sets of beaters revolving about horizontal shafts, the first making 600 and the second 1,200 revolutions per minute. The coarsely broken material from the first beater is passed to a 2-inch screen, the oversize being returned for a second treatment. The material passing through is treated in the second beater, which delivers to a screen. Material exceeding one-sixteenth of an inch in size is returned to the second beater for another treatment.

Texas.—There has been comparatively no appreciable production of asphaltum in this state in recent years. That reported in 1902 was liquid asphaltum.

Utah.—In recent years a small quantity of asphaltic limestone has been produced from deposits in the eastern part of the state, nearly the entire output being consumed in the local markets. The chief asphaltum product, however, is gilsonite (also called grahamite), which is mined about 60 miles from Vernal, Uinta county. Gilsonite is a very high grade material, of especial value for manufacture into varnishes, lacquers, paints, and similar products. On account of the high price it commands, the product can stand a long distance freight rate to chemical works.

Uses.—The principal use for asphaltum is in the construction of pavements. In addition, a considerable quantity is consumed for the manufacture of special varnishes; for waterproofing buildings and other objects as a protection against dampness; for coating vessels, as a protection against the teredo, or ship-boring worm; as an enamel for iron objects; for roofing purposes in the form of asphaltum or tar paper; for electric current insulation; and as an ingredient of cement.

Asphaltum sidewalks were first used in Paris in 1838, and to-day they extend to a distance exceeding in the aggregate 1,200 miles. The introduction of asphaltum pavements in the principal cities of the world is given by J. W. Howard[1] in the following chronological order: Paris, 1854; London, 1869; Budapest, 1871; Dresden, 1872; Hamburg, 1872; Berlin, 1873; followed shortly afterwards by Brussels, Geneva, Leipzig, Frankfort, and others. In the United States a so-called "tar-poultice pavement," composed of coal or gas tar, sand, etc., was laid in several cities during the period from 1870 to 1873, and in 1871 to 1873 successful experiments were carried out with an artificial asphaltic sandstone pavement in New York, N. Y., and in Newark, N. J. In 1878 a pavement composed of Trinidad asphaltum, sand, and powdered limestone was successfully introduced in Washington, D. C., and has since been the standard pavement of that city. At the present time more than a hundred of the principal cities of the United States have adopted some form of asphaltum pavement.

In making asphaltum pavement the general procedure is to grade the street to be paved, roll it with a steam

[1] The Mineral Industry, Vol. II, page 51, et seq.

roller, and then cover it with a layer of cement concrete 5 or 6 inches thick; or in case the street is macadamized or paved with stone blocks, the concrete is unnecessary. In the latter cases a thin layer of asphaltum concrete from 1 to 1.5 inches thick is laid directly upon the old surface. The foundation having been thus prepared, the asphaltum paving mixture, called the "wearing surface," is then spread over it with heated rakes to the desired thickness, which varies from 1.5 to 2.5 inches, depending upon the traffic to pass over it.

The ordinary Trinidad asphaltum paving mixture is made by adding and thoroughly mixing with hot refined asphalt about 15 per cent of its weight of residuum oil, the mixture serving to cement together the sand and powdered limestone which enter into the paving mixture. The proportions of the ingredients vary according to their physical and chemical quality, as well as to the climate in which the pavement is to be used, hot climates requiring less cement than cold. A typical pavement is composed of from 15 to 18 per cent of asphaltic cement, from 70 to 83 per cent of sand, and from 5 to 15 per cent of limestone.

For use in making pavements, the mined asphaltic limestone is crushed into pieces not exceeding 2 inches in diameter, and then reduced to about 10-mesh size in a ball or centrifugal pulverizer. The fine material is heated to 275° F. in heaters, spread over the prepared roadbed, and compressed by heated rammers, or otherwise, until it is of a thickness of from 2 to 2.5 inches. This form of pavement is not popular in places subject to fogs, rains, and low temperatures, for the reason that it becomes polished and slippery when wet, or dry in cold weather. In Paris and Berlin large supplies of sand are kept near the streets paved with asphaltic limestone for use during fog, slight rain, or snow.

Pavements made with Trinidad or other asphaltum in which sand, in proportions up to 80 per cent, is the chief ingredient, do not become slippery except when covered with ice; the sand makes them gritty and not susceptible to polish.

For the manufacture of black varnish, used chiefly for coating ironwork, pure asphaltum is dissolved in benzole or liquids containing benzole. The asphaltum from Syria is used for this purpose. By covering hot iron with asphaltum varnish the volatile ingredients of the latter are driven off, leaving a residual coating in the form of a smooth and polished enamel.

For insulating and cementing purposes asphaltum forms a very important ingredient on account of its wonderfully adhesive quality.

For waterproofing foundations of brick or stone, asphaltum is dissolved in petroleum and laid in the form of a cement or mortar, forming a very durable waterproof coating.

For making cement, petroleum residue is added to asphaltum in order to render it plastic, and from 5 to 10 per cent of sharp sand is mixed with it, according to the purpose for which it is to be used.

For roofing purposes asphaltum is used to a very large extent in admixture with coal tar, pitch, or petroleum residue; the material being used to saturate two or three thicknesses of felt, which are finally compressed into one compact sheet. The tar or roofing felt is held in place by nails driven through tin disks, and the whole completely covered with cement similar in composition to that used in making the felt; while this is still soft a covering of sharp sand, or screened gravel, is spread over the surface, forming a tight roof of great durability.

Asphaltum refining.—There are various methods used for the refining of asphaltum, depending on the nature of the crude material and the use to which it is to be applied. In general, with high grade material, the treatment has for its object the removal of water, volatile hydrocarbons, and mechanically suspended mineral and vegetable matter, but with asphaltums to be used in pavement construction it is essential to allow the mineral matter to remain in the product, for the reason that the asphaltum in this case is to serve solely as a binding and waterproofing material. In fact, asphaltic rock of the proper composition is not refined before use, but merely crushed, heated, and laid in place. The simplest method of extracting asphaltum from its compounds is by boiling in water, which causes the lighter asphaltum to rise to the surface, from whence it can be easily removed. Common salt or calcium chloride may be substituted for water in the treatment of material requiring a higher temperature or a heavier supporting liquid. In other cases asphaltum is extracted by means of a solvent, such as carbon bisulphide or naphtha, and obtained from the solution by heating in stills, which causes the volatile solvent to be distilled for repeated use and leaves the liquid asphaltum residue in a practically pure condition.

TABLE 5.—DETAILED SUMMARY: 1902.

	United States.	California.	Indian Territory.	Kentucky.	All other states.[1]

BAUXITE

BAUXITE.

By Joseph Struthers, Ph. D.

While the production of bauxite in the United States on a commercial scale dates from the opening of the deposits in the state of Georgia during 1889, the mineral does not appear to have been produced in sufficient quantities to be included in the reports of the Eleventh Census. This report, therefore, contains the results of the first census of the mining of bauxite in the United States. Table 1 is a summary of the statistics for 1902.

Table 1.—*Summary: 1902.*

Number of mines or quarries	38
Number of operators	7
Salaried officials, clerks, etc.:	
Number	42
Salaries	$33,230
Wage-earners:	
Average number	150
Wages	$59,763
Contract work	$500
Miscellaneous expenses	$14,939
Cost of supplies and materials	$40,019
Product:	
Quantity, long tons	29,222
Value	$128,206

Of the 38 mines or quarries for which production was reported, 3 were in Alabama, 19 in Arkansas, and 16 in Georgia. The entire number was controlled by 7 operators, of whom 5 were incorporated companies and 2 individual owners. There were 34 mines operated by 3 incorporated companies, 1 company controlling 19, another 10, and another 5 mines. There were 2 companies and 2 individual owners operating 1 mine each. This centralization of the industry makes it impossible to publish the statistics for the different states without disclosing the operations of individual companies; therefore, only the totals for the United States are presented. One mine in Arkansas was reported idle in 1902.

Capital stock of incorporated companies.—A considerable portion of the total production of bauxite was mined by establishments that were engaged in mining operations as incidental to the manufacture of aluminum, paint, and chemical products. The capitalization of these companies represents both their mining and manufacturing industries and, therefore, is not included in this report. Of the 5 incorporated companies, 3 reported that they were engaged primarily in mining. Their authorized capitalization consisted of 2,500 shares of common stock with a par value of $225,000. Of this amount, 1,730 shares, valued at $148,000, had been issued at the close of the year covered by this investigation. No dividends appear to have been paid on this stock during the year.

Employees and wages.—The variation in the number of wage-earners employed during the different seasons of the year and the specified daily rates of pay are shown in Table 4. The height of activity in the industry appears to have been reached during the month of May, when an average of 168 wage-earners was reported. The smallest number, 132, was given for the month of December. The slight variation in the number employed during the entire year indicates a uniform production.

The mining of bauxite requires no particular skill on the part of the miner, and the rates of pay should not be compared with those reported for miners of other minerals where skill and experience are necessary. Of the total number of wage-earners, 77, or 51.3 per cent, were classed as miners. Of this number the wages for 64 ranged from $1 to $1.24 per day. The rates for "all other wage-earners," which includes those engaged in assorting, grading, handling, loading, and hauling the ore and in miscellaneous work in connection with the mining or quarrying of bauxite, were considerably higher than the rates reported for miners. Of the 53 reported for this class, 40 received from $1.50 to $1.74 per day. The rate of pay at which the greatest number of wage-earners was employed is from $1 to $1.24 per day, 69 having been paid at this rate. One hundred and thirty-four, or 89.3 per cent of all wage-earners, received from $1 to $1.74 per day. This uniformity in the rates of pay is due largely to the fact that 69 wage-earners, or 46 per cent of the total number, were reported by 2 operators working on a large scale.

The extraction of bauxite is from open cuts, no tunneling being required, and all of the employees, therefore, were reported as engaged above ground. The 150 wage-earners give an average of 3.95 to each mine, but it is probable that all of the mines were not operated during the entire year. In addition to these wage-earners, 10 others were reported as employed by contractors to whom the sum of $500 was paid.

Supplies, materials, and miscellaneous expenses.—The cost of supplies and materials constitutes an important item of expense in connection with the operation of bauxite mines. The total amount, $40,019, reported for supplies and materials probably includes a considerable proportion of the expenses incident to development work and the installation of new plants and machinery; it includes also the amount spent for supplies used in connection with the calcination of the crude bauxite. The total amount, $14,939, reported as miscellaneous expenses, includes amounts paid for legal services and other miscellaneous items, some of which are not strictly applicable to the operation of the mines.

Mechanical power.—Of the 7 operators from whom returns were received, 6 reported power, all of it owned, for the operation of their mines. The total primary power amounted to 624 horsepower, of which 575 horsepower was supplied by 19 steam engines and 49 horsepower by 2 gas or gasoline engines. There were also 4 electric motors with 64 horsepower.

Production.—The total production for the calendar year 1902, as shown by Table 1, was 29,222 long tons, valued at $128,206. The United States Geological Survey has published annual statistics concerning the quantity and value of bauxite. Table 2 shows the totals for each year since 1889. Since the economic importance of bauxite is due almost exclusively to its use in the manufacture of the metal aluminum, aluminum sulphate, common alum, and artificial emery, this table has been prepared so as to show the available figures for the manufacture of these substances. Statistics for the production of sodium aluminate and other salts that contain aluminum can not be secured.

For all practical purposes the yearly supply of bauxite in the United States, including both domestic production and imports less exports, may be taken as the equivalent of yearly consumption. The aggregate value of the aluminum and alum aluminum sulphate made from bauxite during 1902 amounted to $4,522,761.

TABLE 2.—PRODUCTION, IMPORTS, EXPORTS, AND CONSUMPTION OF BAUXITE AND THE PRODUCTION AND VALUE OF ALUMINUM, 1889 TO 1902, AND OF ALUM AND ALUMINUM SULPHATE, 1889 TO 1902.

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

YEAR.	TOTAL DOMESTIC PRODUCTION.		BAUXITE, IMPORTS.		EXPORTS.		CONSUMPTION.		ALUMINUM, PRODUCTION.		ALUMINUM SULPHATE, PRODUCTION.		ALUM, PRODUCTION.

At the present time most of the bauxite in this country is used as a source of alumina from which the metal aluminum is made. The quantity used in the manufacture of chemical salts is relatively small. Thus the development of the bauxite industry depends to a great extent on the manufacture of aluminum and on the increased use of this metal for purposes of construction requiring lightness and no especial strength. Aluminum is also used as a substitute for copper as a conductor of electricity.

The largest production of bauxite is in France. Next to France ranks the United States, and third comes the United Kingdom, of which Ireland furnishes the output. Table 3 shows the production of the three nations mentioned, for 1900 and 1901, as reported by the United States Geological Survey.

TABLE 3.—*World's production of bauxite: 1900 and 1901.*

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

COUNTRY.	1900		1901	
	Quantity (metric tons).	Value.	Quantity (metric tons).	Value.
Total	87,959	$189,022	106,184	$218,597
United States	23,556	89,676	19,207	79,914
France	58,530	92,596	76,620	124,168
United Kingdom	5,873	6,750	10,357	14,515

The total quantity of bauxite produced in the United States since the beginning of operations in 1889 amounts to 224,691 tons, or an average production of 16,049 tons per year. The greatest quantity produced during one year, 35,280 tons, was reported for 1899. There has been considerable variation in the average price per ton of bauxite, the range having been from $2.58 to $4.38. According to the reports received for 1902, the price varied from $2.50 to $6.50 per ton.

A detailed summary showing the statistics for the production of bauxite during 1902 is given in Table 4.

DESCRIPTIVE.

Occurrence.—The mineral bauxite was first discovered in the year 1821 near Baux, France, by the well-known French chemist, Berthier. He attempted to utilize it in the manufacture of alum, but, because of the large proportion of iron oxide it contained, he was unsuccessful. Later a deposit of the white variety, of greater purity than that of Baux, was discovered at Herault, also in France. The mineral did not, however, become of commercial importance until 1868 or 1869, when Sainte-Claire Deville, a French scientist, in the course of his experiments in the manufacture of aluminum, discovered the value of bauxite as an ore of this metal.

In 1881 occurred the first recorded discovery of bauxite in the United States. The find was made by Edward Nichols, at Hermitage, Floyd county, Ga. Afterwards deposits were found in Polk, Bartow, Gordon, and Chattooga counties. In 1891 R. S. Perry reported the discovery of the mineral in Calhoun county, Ala., although it had previously been found in that state in Cherokee county, where it had been known as iron-ore blossom and as Clinton fossiliferous iron ore. Other deposits were afterwards found in Cleburne county. In 1891, too, the mineral was reported by the Arkansas geological survey as having been found in Saline and Pulaski counties of that state. Other deposits have been found, notably in North Carolina, South Carolina, and New Mexico, but they are too limited in extent, and are too far from transportation facilities, or else contain too many impurities to be of value commercially. Arranged in the order of their outputs, Georgia, Alabama, and Arkansas furnish the total production of the United States.

The mining of the ore in this country is of comparatively recent inception, and, quite naturally, it has not reached a high state of efficiency. The mines are irregular holes dug in the hillsides, with deep, open drainage ditches leading from them. Below the surface the ore is sufficiently soft to be removed with pick and gad, which renders the extraction easy and lessens the cost of production. For a high grade product, however, the uneven quality of the ore makes necessary a sorting by hand or by screens. Screen sorting is generally preferred to hand sorting when the character of the ore will admit of the use of the screen. During the sorting process, when clay is mixed with the bauxite, a common log washer is occasionally used to separate it. The sorted product is then dried in the air or in kilns or furnaces prior to its shipment to market. In this process very satisfactory results have recently been secured from the use of furnaces of the revolving cylindrical type.

Refining was formerly done almost exclusively in Pennsylvania and New York, but recently new refining plants have been erected at Bauxite, in Saline county, Ark., and near East St. Louis, in St. Clair county, Ill. These plants are equipped with modern machinery, and hand labor has been superseded wherever practicable.

France produces three varieties of bauxite: The white of Herault; the pale of Baux and other localities of southern France; and the red, which contains a large proportion of iron oxide, and which is also found in several places in southern France. Of these, the white variety is the purest, containing from 65 to 74 per cent of alumina, from 0.25 to 3 per cent of ferric oxide, and from 12 to 18 per cent of silica. Thus it is comparatively free from iron oxide but contains a relatively large amount of silica. The most impure is the red variety, which contains from 50 to 62 per cent of alumina, from 24 to 28 per cent of ferric oxide, which imparts the red color, and from 1 to 7 per cent of silica. French bauxite is used chiefly in the manufacture of alum and alumina—the white variety, containing but little iron oxide, for alum; and the red variety containing but little silica, after purification, for alumina. Because of the low cost of mining and the low ocean freights of recent years, large quantities of this mineral have been brought to the United States and consumed, mainly for the manufacture of alumina from which metallic aluminum has been made. At the present time there is little, if any, French bauxite used for the manufacture of aluminum sulphate.

In the United Kingdom there are important deposits at Strain, near Ballyclare, and at Glenravel, both in county Antrim, Ireland. Of the European deposits, these are next in importance to those of France. An extensive use of this mineral of county Antrim for the manufacture of aluminum has been retarded, because the high percentage of silica it contains renders it inferior for this purpose to the bauxite of France. It is, however, of excellent quality and contains but little iron oxide or titanic oxide. Much of the product of the Irish mines is consumed in England, where it is made into alum.

In Germany there are several deposits of bauxite of considerable extent, but the quality is inferior to that of the French mineral. In one locality, however, the mineral is quite pure, but the deposit is too small in extent to be commercially valuable.

Austria, Italy, Asia Minor, French Guiana, and New South Wales also possess deposits of the mineral, but as yet none has been developed to the productive stage.

The following statement shows the analyses of specimens from various localities. This statement has been compiled from a large number of analyses which have produced results so varied that the extreme limits of each constituent have been presented. The average quantity of alumina (Al_2O_3) contained in marketed bauxite is practically 58 per cent.

Analyses of specimens of Bauxite from various countries.[1]

LOCALITY.	Alumina, Al_2O_3 (per cent).	Ferric oxide, Fe_2O_3 (per cent).	Silica, SiO_2 (per cent).	Calcium carbonate, $CaCO_3$ (per cent).	Titanium oxide, TiO_2 (per cent).	Water, H_2O (per cent).
France	30.3 to 75	0.1 to 48.8	0.3 to 2.2	0 to 12.7	1.6 to 4	12 to 22.1
Ireland	43.4 to 73	1.96 to 4.26	2.15 to 15.05			18.66 to 40.33
Germany	44.4 to 76.3	2 to 42.9	1 to 44.76			9.7 to 32.33
Austria	58 to 67.6	0.7 to 30	5.9 to 14.4			12.2 to 23.1
Italy	47.4 to 58.9	18.62 to 36.98	2.48 to 4.06		1.27 to 2.86	10.17 to 22.4
Georgia, United States	39.75 to 82.38	0.21 to 13.5	1.34 to 35.83		0.87 to 4.18	16.14 to 32

[1] Compiled from "The Mineral Industry," Vols. I to XI, inclusive.

Chemical properties.—The mineral bauxite is a hydrated aluminum oxide containing also various quantities of iron oxide (Fe_2O_3) and silica (SiO_2). Three varieties are distinguished, the monohydrate (Al_2O_3, H_2O), the dihydrate (Al_2O_3,$2H_2O$), and the trihydrate (Al_2O_3,$3H_2O$). Apart from impurities the composition of these minerals varies from the monohydrate (diaspore), which contains 85.12 per cent of Al_2O_3 and 14.88 per cent of H_2O, to the trihydrate (gibbsite), which contains 65.61 per cent of Al_2O_3 and 34.39 per cent of H_2O. More or less of the alumina in bauxite is replaced by iron or manganese oxides. Silica occurs in the mineral either free or in combination in clay. Minor impurities are compounds of phosphoric acid, sulphur, carbon dioxide, lime, and magnesia. In composition the French mineral appears to correspond to the monohydrate while that of the United States approximates the trihydrate. The composition of bauxite can be determined only by chemical analysis since it is not indicated by the physical properties of the mineral. According to Francis Laur,[1] the average composition is from 66 to 69 per cent of Al_2O_3; 27 per cent of H_2O, SiO_2, and F_2O_3; with from 3 to 4 per cent of TiO_2 and other impurities. In general the value of the ore is in direct proportion to the richness and purity of the alumina content. In ore of good quality the percentage of alumina is high, while that of iron oxide and silica is low. Bauxite has a strong affinity for water, which makes it necessary that the ore be dried before shipment. For the manufacture of aluminum the presence of iron oxide and titanic oxide in the ore is not objectionable, but for making alum these insoluble materials should not exceed 7 per cent, and the iron oxide should be less than 2.75 per cent. The trihydrate, on account of its greater solubility, is best suited for the manufacture of alum, and for this purpose the bauxite of the United States is preferable to that of France.

Physical properties.—Bauxite occurs in the earth's crust in the form of veins, beds, or amorphous masses, not crystallized, and without any constant organoleptic characteristics. The hardness, color, texture, and density often change in the same deposit. Usually the ore occurs in concretionary or pisolitic masses, although it is sometimes a hard, compact, homogeneous fine-grained rock. In some cases the structure is oolitic, and in others it is earthy, resembling clay. It may be hard or soft and compact or porous. The color varies from almost pure white to a deep red or black, passing through shades of cream, gray, yellow, and pink. The mineral is sometimes speckled or mottled, and is more or less stained by iron oxide, manganese minerals, or organic matter. The colors shade into one another gradually or abruptly, and seldom, if ever, does a deposit possess a uniform color. The hardness of average good ore varies from 1 to 3 and the specific gravity from 2.4 to 2.55.

When exposed to extreme heat bauxite becomes so hard that it is almost impossible to make any impression upon it with steel tools. This property in connection with its infusibility makes it an excellent material for crucibles and for furnace linings, since it resists chemical and calorific actions. The chief reason why bauxite is not used more extensively as a basic furnace lining is due to the impurities that are usually present in the mineral.

IMPORTANT PRODUCTS DERIVED FROM BAUXITE.

Four principal substances are prepared from bauxite, viz, aluminum sulphate, alum, artificial emery, and aluminum hydroxide. From the last-named substance the metal aluminum is manufactured.

Aluminum sulphate—$Al_2(SO_4)_3$,$18H_2O$.—This is a chemical salt technically known as "concentrated alum." It is prepared by decomposing bauxite with sulphuric acid. If the mineral is dissolved directly in the acid, the product will contain a large quantity of iron, forming the so-called "alumino-ferric cake," which is used for many purposes where iron and free acid are not objectionable, as in the precipitation of sewage and of waste liquors from dyeworks. Pure aluminum sulphate is now generally prepared by the Bayer process, which consists in adding powdered alumina to the solution of sodium aluminate, containing 1 part of Al_2O_3 to 1.8 parts of Na_2O. The reaction causes a crystalline precipitate of aluminum hydroxide. The silica and the iron present remain dissolved in the solution. The precipitated aluminum hydroxide is separated from the solution and is thoroughly washed and later dissolved in pure, hot, concentrated sulphuric acid until the frothing ceases. The solution is then transferred to shallow leaden pans and allowed to cool; thus the pure aluminum sulphate is separated out in the form of a solid crystalline mass. Owing to its greater purity and greater strength, aluminum sulphate has largely replaced alum in the arts. Aluminum sulphate is extensively used as a mordant in dyeing; in preparing

[1] Transactions of the American Institute of Mining Engineers, Vol. XXIV (1894), page 237.

size for paper; for making alum and aluminum salts (red liquor, etc.); in tawing skins; for precipitating sewage or coloring matter in water; and, in general, for all purposes in which alum was formerly used.

Potassium alum — $K_2SO_4,Al_2(SO_4)_3,24H_2O$. — This product is known also as "potash alum" and "common alum." The manufacture of alum from bauxite involves the preparation of a pure solution of aluminum sulphate to which is added the proper proportion of an alkali sulphate in order to form the special alum desired. Thus potassium sulphate is used to form potassium alum and sodium sulphate for sodium alum. All alums crystallize from solutions perfectly, forming very pure crystals even from impure solutions, and it is because of this property that the alums are so extensively used in the arts. The chief uses of common alum are as a mordant in dyeing; in preparing size in paper making; in tawing skins; in making pigment lakes; for clarifying turbid liquors; for precipitating sewage waters; and for hardening plaster of Paris casts and other forms. For these uses, however, as mentioned above, aluminum sulphate is generally preferred because of its greater strength and solubility.

Aluminum hydroxide—$Al_2(OH)_6$.—The manufacture of aluminum hydroxide from bauxite is of great importance, because by a simple calcination it yields aluminum oxide (alumina), which is the chief crude material used for the manufacture of the metal aluminum. In making aluminum hydroxide, bauxite is roasted, pulverized, and mixed with calcined soda ash in the proportion of 1 part of Al_2O_3 to 1.1 parts of Na_2O, or greater if silica be present in the ore. The mixture is calcined at a white heat for three or four hours until all traces of carbon dioxide and water have been expelled. The calcined product is then ground and lixiviated with hot water; this process yields a solution of sodium aluminate from which the aluminum hydroxide is precipitated by passing carbon dioxide gas through it. The impurities, silica and iron oxide, remain dissolved in the mother liquor.

In order to avoid the costly and tedious chemical process of obtaining pure aluminum hydroxide, an electric furnace method has been recently patented by Mr. Charles M. Hall,[1] whereby the impurities in the bauxite, mainly iron oxide and silica, are removed, and the bauxite is thus purified for the aluminum reduction process. The process of purifying the bauxite consists in submitting it to a preliminary heating for some hours in the presence of carbon and metallic aluminum in an electric furnace, during which time the iron oxide and the silica become reduced to metallic iron and silicon and combine with the aluminum to form a heavy alloy, which can be detached easily from the mass of purified bauxite after it has cooled.

Artificial emery.—Within the past year or so a company at Niagara Falls, N. Y., has consumed a considerable quantity of bauxite for the manufacture of abrasive wheels.

[1] United States patents Nos. 677,207, 677,208 (July, 1901), and No. 706,553 (August, 1902).

FLINT AND FELDSPAR

FLINT AND FELDSPAR.

By Story B. Ladd.

The chief consumption of both flint (or quartz) and feldspar is in the pottery industry, and as the mining of these minerals is in some cases associated, the general statistics of the two industries are presented together, as well as separately.

Table 1 is a combined summary of the statistics for the flint and feldspar industries for 1902.

Table 1.—*Summary: 1902.*

Number of mines or quarries	46
Number of operators	43
Salaried officials, clerks, etc.:	
Number	45
Salaries	$34,425
Wage-earners:	
Average number	371
Wages	$154,898
Miscellaneous expenses	$33,698
Cost of supplies and materials	$68,920
Product:	
Quantity, short tons	81,652
Value	$394,633
Flint—	
Quantity, short tons	36,365
Value	$144,209
Feldspar—	
Quantity, short tons	45,287
Value	$250,424

Of the 46 mines, 18 produced flint, 23 feldspar, and 5 both flint and feldspar. Of these 5 mines, 4 were in Maine and 1 in Massachusetts. Feldspar was the chief product of the 4 mines in Maine, which also produced 1,254 short tons of flint, valued at $2,593, as a by-product; and flint was the chief product of the 1 mine in Massachusetts, with 112 short tons of feldspar, valued at $1,000, as a by-product. One corporation operated a feldspar and flint mine in Maine and a flint mine in Pennsylvania; 1 corporation operated a feldspar and flint mine in Maine and a flint mine in Maryland; and 1 corporation operated feldspar mines in Pennsylvania and Maryland.

The details of the capital stock of 9 of the 11 incorporated companies are shown in the following table:

[1] Includes companies distributed as follows: Connecticut, 2; Maine, 3; Maryland, 2; Massachusetts, 1; Pennsylvania, 3.

[2] Includes companies distributed as follows: Connecticut, 2; Maine, 2; Maryland, 2; Massachusetts, 1; Pennsylvania, 2.

One of these 11 companies, mining feldspar in Pennsylvania, was not engaged chiefly in mining or quarrying, and its capitalization was not reported. Also 1 of the companies mining feldspar and flint in Maine was a large clay producer in Delaware, and its capitalization appears under the clay statistics. Both flint and feldspar were produced by 2 of the companies in Maine and 1 in Massachusetts; 6 of the companies mined feldspar only, and 2 mined flint only.

FLINT.

The statistics for flint or quartz presented herewith do not include those for crystalline quartz, which is used principally as an abrasive, or as a wood finisher, and which is separately considered in the class of abrasive materials.

The flint or quartz production of the United States in 1902, that is, the flint mined or quarried as such,

with the exception above noted, amounted to 36,365 short tons, valued at $144,209. In 1889 the production of flint was 11,113 long tons, or 12,448 short tons, valued at $49,137. At the census of 1880 the production of "quartz and feldspar" was reported as 21,571 long tons, valued at $103,878.

The crystalline quartz production for the year 1902 was 15,104 short tons, valued at $43,085, which, added to the flint production, makes a total of 51,469 tons, valued at $187,294, for the combined production of flint and crystalline quartz for 1902. The production of quartz as a whole has therefore increased from 12,448 short tons in 1889, to 51,469 short tons in 1902, or over 300 per cent; and the value from $49,137 to $187,294, or over 280 per cent. The average price in 1889 was $3.95 per short ton; and in 1902, the average price for the entire quartz production, flint and crystalline quartz combined, was $3.64 per short ton.

There were 19 active flint mines or quarries located—4 in Connecticut, 6 in Maryland, 4 in Pennsylvania, 2 in New York, and 1 each in Massachusetts, Montana, and Virginia. These were controlled by 17 operators—10 individuals, 4 firms, and 3 incorporated companies.

There were 6 operators who reported no flint mined during the year—3 individual operators in Connecticut, 1 individual operator in Maryland, 1 individual operator in New York, and 1 incorporated company in Wisconsin, which was engaged chiefly in the production of clay, but in former years had produced a small amount of flint as a by-product.

Employees and wages.—The wage-earners constituted 86.9 per cent of the salaried employees and wage-earners, and their wages were 76.8 per cent of the total salaries and wages.

The average number of wage-earners employed during each month is shown in Table 5. The least number was employed during the winter months and the largest number during the summer months, though the range was not large, the minimum being 91 in December and the maximum 138 in July.

The average number of wage-earners employed at specified daily rates of pay is also shown in Table 5. The mines that produced flint or quartz as such, with the exception of the mine in Montana, were located in the Atlantic coast states and the product is chiefly used by the pottery industry, which is chiefly confined to the states east of the Mississippi. Of the wage-earners 71 per cent received less than $1.50 per day, 22 per cent $1.50 to $1.99 per day, and but 8 per cent $2 and over. Of the 65 miners or quarrymen 58 received from $1 to $1.74 per day, and only 7 received $1.75 and over. Of the latter, 4, at $3 to $3.24, were in Montana.

Supplies, materials, and miscellaneous expenses.—The cost of supplies and materials was reported as $18,642, and the miscellaneous expenses as $14,291. Of the latter, the sum of $5,813 was paid by 11 mines for royalties and rent of mine and mining plant, these mines being located, 2 in Connecticut, 3 in Maryland, 4 in Pennsylvania, and 1 each in New York and Virginia; and the sum of $8,478 by 17 mines for rent of offices, taxes, insurance, interest, and other sundries.

Mechanical power.—Of the 23 mines or quarries, 8 employed power aggregating 740 horsepower, of which 155 horsepower was furnished by 4 steam engines, and 585 horsepower by 10 water wheels. The waterpower was reported for 5 mines in Maryland and 1 mine in Massachusetts.

Production.—The total production for the year 1902 was 36,365 short tons, valued at $144,209. This consisted of 20,295 tons of crude flint, valued at $35,046, an average of $1.73 per ton, and 16,070 tons of ground flint, valued at $109,163, an average of $6.79 per ton. Montana was the largest producer in quantity, with 10,640 short tons of crude flint, valued at $14,250. The production of Maryland and Pennsylvania was approximately the same, each 26.9 per cent of the total, but Maryland produced 49.2 per cent of the ground flint, and Pennsylvania 34.5 per cent. The United States Geological Survey has published annual statistics showing the quantity and value of flint produced since 1892, and in the following table there is shown the total production and value for each year:

TABLE 3.—*Production of flint: 1892 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

YEAR.	Quantity (short tons).	Value.
1892	22,400	$80,000
1893	33,231	63,792
1894	42,560	319,200
1895	13,747	21,038
1896	12,458	24,226
1897	13,466	26,227
1898	21,425	42,670
1899	29,852	180,345
1900	32,495	86,351
1901	34,420	149,297
1902	36,365	144,209

The average price of flint per ton is so variable, ranging from a minimum of $1.53 in 1895 to a maximum of $7.50 in 1894, that no comparison can be made as to values. The largest production was in 1894, when it reached 42,560 short tons, and the smallest was 12,458 short tons in 1896. Since 1896, the production shows a steady increase year by year. The average price of crude flint in 1900, 1901, and 1902 was practically stationary, varying only from $1.73 to $1.86 per ton, while the average price of ground flint increased from $3.73 per ton in 1900 to $6.72 per ton in 1901, and $6.79 per ton in 1902.

The value of the imports for consumption of flint and flint stones, unground, for the fiscal years ending June 30, 1900, 1901, and 1902, respectively, were $40,475, $64,697, and $85,092. The imports were chiefly from France, Denmark, and Belgium, in the order named, with more than half the values coming from France, and a small amount from Germany.

A detailed summary of the statistics for flint is given in Table 5.

Occurrence and use.—Although silica or quartz is

widely distributed in igneous and metamorphic rocks, and constitutes the gangue of many metalliferous veins, yet it is only the pure non-ore bearing quartz veins that are chiefly drawn upon for the quartz production of the United States. Many quartzites or sandstones are of sufficient purity to be ground for potters' use.

The term flint, as properly used, refers to the cryptocrystalline variety of silica occurring in nodular masses in calcareous strata, particularly in chalk. This is found in the United States in Texas and Arkansas and Florida, but is not at present utilized. The mineral worked throughout the entire Appalachian region, either for pottery or under the name of "flint," and included in this report, is quartz. The imported flint, on the other hand, is in part, if not wholly, the true flint from the chalk cliffs.

Flints when calcined and ground to powder enter into the composition of many kinds of fine pottery and were formerly employed in the manufacture of the finer varieties of glass, hence termed "flint glass."

The manufacture of gunflints was formerly an important industry, and the use of flints in the "stone age" and the later periods for the manufacture of axes, knives, spearheads, arrowheads, and the like, forms one of the most interesting fields of research for the antiquary and archaeologist.

The flint product, like feldspar, is used chiefly in the pottery and porcelain industry, though some is consumed in the manufacture of scouring soaps and wood fillers.

FELDSPAR.

The feldspar product of the United States for the year 1902 amounted to 45,287 short tons, of a value of $250,424. In 1880 the production was included in "quartz and feldspar," cited under "Flint" in this report. The only statistics pertaining to the feldspar production reported at the Eleventh Census, for the year 1889, with which comparison can be made are the quantity produced and its value. The production was 6,970 long tons, or 7,806 short tons, valued at $39,370. The average prices for all material, crude and ground, for the census years 1889 and 1902, were $5.04 and $5.53 per short ton, respectively. There has been a very considerable increase in the production during the last decade, with slight increase in average value.

As shown by Table 6, Pennsylvania had the largest number of feldspar mines or quarries, 12 in number, and produced one-third of the entire feldspar product and approximately one-half of the ground feldspar.

There were 9 idle mines in 1902. Of the operators, 7 were individuals, 4 in Pennsylvania and 1 each in Alabama, Connecticut, and New York; 1 was an incorporated company in New York, and 1 a firm (limited partnership) in Connecticut. The capital stock of the incorporated company was 200,000 shares, all common stock, of a par value of $200,000, authorized; of which 150,000 shares, of a par value of $150,000, had been issued. The power of the idle establishments aggregated 42 horsepower, reported by 1 operator in Connecticut and 1 in New York.

Employees and wages.—The wage-earners constituted 90.3 per cent of the salaried employees and wage-earners, and their wages were 84.2 per cent of the total salaries and wages. The average number of wage-earners employed by months is shown in Table 6. The maximum number, 279, appears in July, and the minimum, 227, in February, with an average of 252. Boys under 16 years of age were employed in two cases; 1 mine in Pennsylvania employed an average of 2 for the year, and 1 mine in Maryland an average of 1.

The average number of wage-earners employed at specified daily rates of pay is also shown in Table 6. The mines producing feldspar were all located in the Atlantic coast states, and, moreover, were all surface mines, no underground working being reported; hence the wages paid were comparatively low. Of the wage-earners, 61 per cent received less than $1.50 per day; 32 per cent from $1.50 to $1.74, and but 7 per cent $1.75 and over. Of the 183 miners or quarrymen, who constituted 73 per cent of all wage-earners, 69 per cent received not to exceed $1.49 per day and 30 per cent from $1.50 to $1.74; only 3 miners received $1.75 or more.

Supplies, materials, and miscellaneous expenses.—The cost of supplies and materials was $50,278, and the miscellaneous expenses, $19,407. Of the latter the sum of $10,584 was paid by 14 mines for royalties and rent of mine and mining plant, these mines being located—4 in Connecticut, 2 in Maine, 2 in Maryland, and 6 in Pennsylvania; and $8,823 by 19 mines for rent of offices, taxes, insurance, interest, and other sundries.

Mechanical power.—Of the 27 mines or quarries, 13 employed power aggregating 1,204 horsepower, of which 854 horsepower was furnished by 15 steam engines and 350 horsepower by 7 water wheels. The waterpower was reported for 2 mines in Connecticut, 1 in Maine, and 1 in Pennsylvania.

Production.—The total production for 1902 was 45,287 short tons, valued at $250,424. This consisted of 21,870 short tons of crude feldspar, valued at $55,501, an average of $2.54 per ton, and 23,417 short tons of ground or prepared feldspar, valued at $194,923, an average of $8.32 per ton.

Of the several producing states Pennsylvania reported the largest amount, constituting 33 per cent of the total quantity, 29 per cent of the total crude product, and 37 per cent of the total ground product. Connecticut was the next in rank, producing 31 per cent of the total quantity, 24 per cent of the total crude product, and 37 per cent of the total ground product. Maine produced 19 per cent of the total product, 21 per cent of the total crude product, and 16 per cent of the total ground product.

The United States Geological Survey has published annual statistics of the quantity and value of feldspar produced since 1892, and they are shown in Table 4.

TABLE 4.—*Production of feldspar: 1892 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

YEAR.	Quantity (short tons).	Value.
1892	16,800	$75,000
1893	20,578	68,307
1894	19,264	167,000
1895	8,523	30,000
1896	10,203	35,200
1897	12,516	43,100
1898	13,440	32,395
1899	24,202	211,545
1900	24,821	180,971
1901	34,741	220,422
1902	45,287	250,424

For the years 1892 to 1899, inclusive, the production of the combined product of crude and ground feldspar and the average price per ton was so variable, ranging from a minimum of $2.41 per short ton for 1898 to a maximum of $8.74 per short ton in 1899, that no comparisons can be made as to values. In 1893 the production aggregated 20,578 short tons, succeeded by a drop to 8,523 short tons in 1895. Since 1895 there has been an increase, year by year, of the total quantities. The average price of crude feldspar per ton was $4.06 in 1900, $2.18 in 1901, and $2.54 in 1902. The price of ground feldspar per ton shows a slight increase, advancing from $7.54 in 1900 to $8.01 in 1901 and $8.32 in 1902.

There was some importation of feldspar from Canada, but not being separately returned to the Treasury Department the statistics can not be given.

A detailed summary of the statistics for feldspar is given in Table 6.

Occurrence and use.—The members of the group of feldspar, or feldspars, are anhydrous double silicates, consisting of a silicate of alumina combined with a silicate of potash, soda, or lime, or with two or all of these. In all the members of the group there exists the simple relation of one atom of the sesquioxide, alumina, to one of the protoxide base or bases, but the proportion of silica varies considerably in the different species. The highly silicated species, as orthoclase, albite, and oligoclase, occur in granite, trachytes, and other so-called acid rocks, while the less silicated feldspars, as labradorite, are confined to basalts and other basic rocks.

Orthoclase is the most ordinary species, and is the one most commonly used in this country. It is a potash feldspar, of which a typical analysis from Bedford, N. Y., is: Silica, 64.97; alumina, 20.85; alkalies, 13.72; and water, 0.46=100.

Labradorite is a soda-lime feldspar, consisting of silica, 55.75; alumina, 26.50; lime, 11; soda, 4; peroxide of iron, 1.25; water, 0.50=99.

The feldspars fuse, when exposed to a high temperature, to a vitreous enamel possessing considerable hardness, a property which has led to their use in glazing pottery. The chief consumption of feldspar is in the manufacture of pottery and tiles, although it is also used in the manufacture of wood fillers, scouring soaps, and in glass manufacture.

[2] One company operated 2 mines, 1 each in Pennsylvania and Maryland.

FULLER'S EARTH

(1003)

FULLER'S EARTH.

By Story B. Ladd.

Fuller's earth was first discovered in the United States at Quincy, Fla., in 1893, and the production is now for the first time reported at a United States census. Table 1 is a summary of the statistics for the year 1902.

Table 1.—*Summary: 1902.*

Number of mines	4
Number of operators	4
Salaried officials, clerks, etc.:	
Number	14
Salaries	$10,040
Wage-earners:	
Average number	111
Wages	$33,775
Contract work	$4,021
Miscellaneous expenses	$2,057
Cost of supplies and materials	$28,966
Product:	
Quantity, short tons	11,492
Value	$98,144

There were only 4 mines in operation, 2 each in Arkansas and Florida, the latter state producing 90.4 per cent of the total quantity. The production for 1902 was 11,492 short tons, valued at $98,144, or an average of $8.54 per ton, the minimum being $8 and the maximum $13.33. The 4 mines were controlled by 1 individual operator and 3 incorporated companies. There were 2 idle mines in 1902—1 in Georgia and 1 in New York.

Capital stock of incorporated companies.—The following table presents the details of the capitalization of the incorporated companies:

Table 2.—*Capitalization of incorporated companies: 1902.*

Number of incorporated companies	[1] 3
Number reporting capitalization	[2] 2
Capital stock:	
Total authorized—	
Number of shares	3,200
Par value	$230,000
Total issued—	
Number of shares	3,200
Par value	$230,000
Common—	
Authorized—	
Number of shares	2,200
Par value	$130,000
Issued—	
Number of shares	2,200
Par value	$130,000
Preferred—	
Authorized—	
Number of shares	1,000
Par value	$100,000
Issued—	
Number of shares	1,000
Par value	$100,000

[1] Includes 1 company in Arkansas and 2 in Florida.
[2] Includes 1 company in Arkansas and 1 in Florida.

All of the stock authorized—3,200 shares, having a par value of $230,000—has been issued. No dividends were reported.

Employees and wages.—The average number of wage-earners employed during each month, and their specified daily rates of pay according to occupations, are shown in Table 4. The large increase in the number of men employed for the last four months of the year was due to the beginning of operations by a new producer. Eliminating the men employed by this new operator, it appears that the busiest month was January, while the industry was at its lowest ebb in July.

As the excavation of fuller's earth requires no skill, the rates of pay should not be compared with those in mining industries requiring skill and experience. The rates for miners are only those ordinarily received by unskilled day laborers. Of the 54 miners employed, 81.5 per cent received less than $1.25 per day, and the remaining 18.5 per cent from $1.25 to $1.99 per day. Eight employees were engaged in contract work, for which $4,021 was expended.

Supplies, materials, and miscellaneous expenses.—The cost of supplies and materials was $28,966; the miscellaneous expenses amounted to $2,057, all for rent of offices, taxes, insurance, interest, and other sundries.

Mechanical power.—For the 4 mines 460 horsepower was reported, supplied by 7 steam engines with a capacity of 430 horsepower, and 2 gas or gasoline engines with a capacity of 30 horsepower. All of the gas or gasoline power and 80 per cent of the steam power were reported from Florida.

Production.—The production for the year 1902 was 11,492 short tons, valued at $98,144. The United States Geological Survey has published annual statistics showing the quantity and value of fuller's earth produced. In the following table these, together with the statistics of imports of both the crude and manufactured article, with the average value per ton, are shown from 1898 to 1902. Quantities are shown in short tons for purposes of comparison.

TABLE 3.—PRODUCTION AND IMPORTS OF FULLER'S EARTH: 1898 TO 1902.

YEAR.	PRODUCTION.			IMPORTS.[1]

[1] Quantities have been converted into short tons for purposes of comparison.

For each year except 1902 the domestic production slightly exceeded the imports, the percentage of the total consumption—production and imports—which was produced in the United States being 61 in 1898, 52 in 1899, 51 in 1900, 54 in 1901, and 43 in 1902.

During the period from 1897 to 1902 the average value of imports per short ton ranged from a minimum of $6.03 in 1899 to a maximum of $7.59 in 1898; the average value of fuller's earth imported in a crude state—unwrought or unmanufactured—ranged from a minimum of $5.27 in 1901 to a maximum of $6.97 in 1898, while the average value of the wrought or manufactured earth imported ranged from a minimum of $6.31 in 1899 to a maximum of $8.37 in 1897. During the period from 1867 to 1883 the average value per short ton of imports of fuller's earth, based upon the custom house returns to the Treasury Department, ranged from a minimum of $9.77 in 1870 to a maximum of $11.25 in 1882, with an average of $10.59 for the entire period.

Table 4 is a detailed summary for the industry in 1902.

DESCRIPTIVE.

Fuller's earth derives its name from having been used in fulling cloth and wool and cleansing them of grease; it was also used by furriers for cleansing furs. It is a variety of clay resembling other clays in appearance, but commonly lacking plasticity. It is fine grained, of variable color, of a specific gravity of from 1.8 to 2.2, and has strong absorbent properties.

The composition of fuller's earth varies considerably, but this variation may be due in part to impurities. As a rule there is a high percentage of combined water; this is most marked in the case of the foreign product. The following analyses show the composition of samples, both domestic and foreign:

Analyses of fuller's earth.[1]

CONSTITUENT.	Gadsden county, Fla.	Decatur county, Ga.	Reigate, England.	Enid, Okla.	Fairburn, S. Dak.	Sumter, S. C.

Moisture	6.41	6.41	.....	.....	2.30	2.50

[1] United States Geological Survey, "Mineral Resources of the United States," 1901, pages 933 and 934.

A variety of fuller's earth occurring in the island of Argentiera, Greece, has been mined since ancient times. In England there is an argillaceous deposit 150 feet thick, extending from Dorsetshire to Bath and Cheltenham. Fuller's earth is mined especially near Reigate, in Surrey, and at one time was considered of such importance that its exportation was prohibited under severe penalties.

The discovery of fuller's earth in Florida in 1893 caused much excitement, and a search was made for other deposits. The deposit at Quincy, Gadsden county, in that state, extending through Leon county and into Decatur county, Ga., still ranks first in commercial importance. But beds, varying widely in character, have been found in Hillsboro, Manatee, and Marion counties, Fla.; Columbia county, Ga.; Sumter county, S. C.; Oneida county, N. Y.; Saline county, Ark.; Garfield county, Okla.; Custer county, S. Dak.; Cherry county, Nebr.; Fremont county, Colo.; Kern county, Cal.; and in Utah. The Florida and Georgia deposits, which are very similar, do not resemble the English product. The fuller's earth of South Dakota, however, is almost identical with the English earth, and mines in that state will probably in time become important producers.

The methods of mining fuller's earth and preparing it for the market are very simple. The overburden of sand and worthless plastic clay is removed, and the wet fuller's earth is chopped out in thin slices with mattocks and dried in the sun. The wet, greenish clay loses perhaps half of its weight, changes to a creamy white color, and becomes very brittle, easily splitting into thin layers. Artificial driers and an arrangement for grinding the earth to the requisite degree of fineness have been recently introduced.

The Florida earth, ground to 60 mesh or finer, is used almost entirely as a substitute for boneblack in filtering mineral lubricating oils. The common practice is to run the earth into long cylinders, through which the crude black mineral oils are allowed to percolate very slowly. The oil which comes out first is water white in color and much thinner than that which follows.

While the Florida earth is superior to the English variety for the refining of mineral oils, the English product is much more desirable for the treatment of animal and vegetable oils. The process is radically different. The oil is heated in large tanks to a tem-

perature above the boiling point of water, and from 5 to 10 per cent of its weight of fuller's earth, ground to 120 mesh, is added; the mixture is stirred vigorously for twenty minutes and then filtered off through bag filters.

Perhaps the most remarkable feature of filtration by the use of fuller's earth is the fact that—even in the mixture of oils present in crude petroleum—the oil which first percolates through the earth is the lowest in specific gravity. Indeed, the separation which can be secured by this process is comparable with the results of fractional distillation.

TABLE 4.—*Detailed summary: 1902.*

Number of mines	4
Number of operators	[1] 4
Character of ownership:	
Individual	1
Incorporated company	3
Salaried officials, clerks, etc.:	
Total number	14
Total salaries	$10,000
General officers—	
Number	2
Salaries	$3,500
Superintendents, managers, foremen, surveyors, etc.—	
Number	9
Salaries	$5,000
Clerks—	
Number	3
Salaries	$1,500
Wage-earners:	
Total average number (above ground)	114
Total wages	$33,775
Engineers, firemen, and other mechanics—	
Average number	12
Wages	$6,335
Miners—	
Average number	54
Wages	$17,140
Boys under 16 years—	
Average number	24
Wages	$3,725
All other wage-earners—	
Average number	24
Wages	$6,575
Average number of wage-earners at specified daily rates of pay:	
Engineers—	
$1.50 to $1.74	1
$2.00 to $2.24	2
$3.00 to $3.24	1
Average number of wage-earners at specified daily rates of pay—Continued.	
Firemen—	
$1.00 to $1.24	3
$1.50 to $1.74	2
Machinists, blacksmiths, carpenters, and other mechanics—	
$1.50 to $1.74	3
Miners—	
$0.75 to $0.99	15
$1.00 to $1.24	29
$1.25 to $1.49	2
$1.50 to $1.74	5
$1.75 to $1.99	3
Boys under 16 years—	
$0.75 to $0.99	24
All other wage-earners—	
$0.75 to $0.99	15
$1.00 to $1.24	5
$1.25 to $1.49	4
Average number of wage-earners employed during each month:	
Men 16 years and over—

GRAPHITE

(1009)

30223—04——64

GRAPHITE.

By Joseph Struthers, Ph. D.

Statistics for the mining of graphite were first reported separately at the census of 1880. Table 1 shows the comparative statistics of the mining operations for 1880, 1889, and 1902.

Table 1.—*Comparative summary: 1880 to 1902.*

	1902	1889	1880
Number of mines	28	(1)	3
Number of operators	19	(1)	(1)
Salaried officials, clerks, etc.:			
Number	27	(2)	(2)
Salaries	$18,924	(2)	(2)
Wage-earners:			
Average number	164	101	93
Wages	$76,729	$38,329	$29,600
Miscellaneous expenses	$6,039	$6,393	(1)
Cost of supplies and materials	$51,840	$7,734	$2,900
Product: [3]			
Quantity, short tons	27,438	7,003	[4] 940
Value	$227,508	$72,662	$49,800

[1] Not reported.
[2] Not reported separately.
[3] The United States Geological Survey reports 3,936,824 pounds of crystalline, valued at $126,144, and 4,739 short tons of amorphous, valued at $55,964, these representing the product marketed, while the Census figures represent the product mined.
[4] Does not include the return for one large producer in New York, received too late for tabulation.

The states reporting production in 1880 were New York, North Carolina, and Pennsylvania. In 1889 there is no record of production in North Carolina, but operations in Michigan, New York, Pennsylvania, Rhode Island, and Wyoming were reported. In 1902 mining operations were carried on in 13 states—Alabama, Georgia, Massachusetts, Michigan, Montana, New Mexico, New York, North Carolina, Pennsylvania, Rhode Island, South Dakota, Wisconsin, and Wyoming. The period between 1880 and 1889 does not show so great a development of the industry as that between 1889 and 1902, the increase in the value of production being 213.1 per cent in the later period, as compared with 45.9 per cent in the earlier one; this advance was due largely to the increased demand for graphite in the arts.

There were 12 mines—5 in New York, 3 each in North Carolina and Pennsylvania, and 1 in Alabama—reported as idle during 1902, and 3—1 each in New Hampshire, New York, and Pennsylvania—at which development work was done.

Capital of incorporated companies.—Fifteen of the 19 active operators were organized as incorporated companies. The details of the capitalization of these companies are shown in the following table:

Table 2.—*Capitalization of incorporated companies: 1902.*

Number of incorporated companies	[1] 15
Capital stock and bonds issued	$2,632,800
Capital stock:	
Total authorized—	
Number of shares	1,571,640
Par value	$2,914,000
Total issued—	
Number of shares	1,299,688
Par value	$2,614,800
Dividends paid	$8,750
Common—	
Authorized—	
Number of shares	1,470,140
Par value	$2,664,000
Issued—	
Number of shares	1,218,188
Par value	$2,384,800
Dividends paid	$8,750
Preferred—	
Authorized—	
Number of shares	101,500
Par value	$250,000
Issued—	
Number of shares	81,500
Par value	$230,000
Bonds:	
Authorized—	
Number	40
Par value	$20,000
Issued—	
Number	36
Par value	$18,000
Interest paid	$1,080
Assessments levied	$1,000

[1] Includes companies distributed as follows: Alabama, 1; Georgia, 1; Massachusetts, 1; Michigan, 2; Montana, 1; New Mexico, 1; New York, 3; Pennsylvania, 2; Rhode Island, 1; South Dakota, 1; Wisconsin, 1.

The total par value of stock and bonds issued was $2,632,800; of this amount 90.5 per cent represents the value of common stock, 8.7 per cent the value of preferred stock, and the remaining eight-tenths of 1 per cent the value of the bonds. The dividends paid during 1902 represent three-tenths of 1 per cent of the par value of stock issued, and the $1,080 paid as interest on bonds constitutes 6 per cent of the par value of all bonds issued.

Employees and wages.—The average number of wage-earners employed during each month of 1902, and their daily rates of pay by occupations, are shown in Table 5. The minimum number of wage-earners shown for any month during the year was in January, 137 men and 1 boy; the maximum number in October, 185 men and 1 boy. Judging by the slight variation in the number of employees, the production, although below the average during the winter and spring months, must have been fairly steady.

Of the total number of wage-earners, 34.8 per cent were paid at rates less than $1.50 per diem, and 65.2 per cent at higher rates. Of the total number, engineers formed 4.8 per cent; machinists, blacksmiths, car-

penters, and other mechanics 11 per cent; and miners, the largest class, 53 per cent.

Mechanical power.—A total of 769 horsepower was reported for this industry; 749 horsepower was furnished by 18 steam engines and 10 horsepower by 1 water wheel, while 10 electric horsepower was rented.

Production.—Although the production of graphite has had a very important bearing upon the development of several of the metallic industries in the United States, it was not until 1880 that authentic statistics of production were collected. Since the quantities of graphite which have been exported from the United States are so small as to be negligible in this connection, for all practical purposes the total consumption of graphite within the United States may be assumed as equivalent to the production plus the importation. Table 3, compiled from the reports of the United States Geological Survey, gives the marketed production of natural graphite in the United States, together with the imports, for the period 1880 to 1902, with the production of artificial graphite since 1897. The statistics of production here shown differ from Census figures in that they represent only the marketed output and not the actual quantity mined.

TABLE 3.—PRODUCTION AND IMPORTS OF GRAPHITE: 1880 TO 1902.

The detailed statistics of the industry for 1902 are shown in Table 5.

DESCRIPTIVE.

The name graphite is derived from the Greek γράφειν, "to write," and refers to the use of the mineral for that purpose. Graphite is sometimes called "plumbago" or "black lead," because of its lead-like appearance, although it contains no lead. Graphite was known to the ancients. Up to the latter part of the eighteenth century, however, the names plumbago and molybdena seem to have been applied indiscriminately to graphite and to molybdenite (molybdenum sulphide, MoS_2), both of which leave a black mark when rubbed on paper. Graphite appears to have been first distinguished as early as 1565, by Conrad Geissner, but the popular misconception as to the two substances prevailed until 1779, when the famous chemist Scheele showed them to be entirely distinct.

Physical and chemical characteristics.—Graphite occurs as a form of carbon, and constitutes the last stage in the mineralization of vegetable matter. In the first stage of this process the woody tissue is converted into peat; the peat to a lignite; the substance then passes through the range of bituminous coals to semianthracite, anthracite, graphitic anthracite, and finally it is converted into graphite, which is practically pure carbon. There is no strict line of demarcation between these various forms of carbon, which merge gradually into one another. In structure and purity, specimens from different deposits show a wide divergence.

The mineral occurs in two forms, the crystalline and the amorphous. Crystalline graphite is usually found in a compact foliated or granular mass. At times the crystals are in the form of distinct hexagonal plates. The amorphous variety is, as its name implies, without crystalline structure. The term has been used to include a wide range of natural carbonaceous products—such as the graphitic anthracite of Rhode Island, which is of a structure between scaly and granular, and selected samples of which contain as much as 52 per cent of carbon; and the so-called Baraga graphite of Michigan, which in reality is a carbonaceous schist. The crystalline variety consists of finer grades, and hence is used where softness and a smooth uniformity of structure are desirable, as for lubricants or in the better grades of pencils.

Graphite is iron-black or steel-gray in color and has a metallic luster; to the touch it is smooth and soap-like. Its specific gravity varies from 2.015 to 2.583, the variation being due to the impurities—such as iron oxide, alumina, magnesia, lime, and silica—which are present in all natural graphite. Usually, there is also from five-tenths of 1 per cent to 1.3 per cent of hydrogen—a fact which seems to point to an organic origin. Graphite is infusible, and resists the corrosive action of many chemicals and molten metals. These properties render the crystalline variety, with its flake-like form, of great value in the manufacture of graphite crucibles for special purposes—for instance, to resist intense heat in the manufacture of crucible steel; to possess great density at a high heat, as in the refining of gold and silver; and to resist the corrosive action of easily oxidized metals and alloys in a molten condition, as in melting brass, bronze, etc. Although crystalline graphite will burn in oxygen at and above a temperature of 575° C., it is a good conductor of heat and electricity; this property renders it of special value for the manufacture of the commutator brushes used in electrical machines, for use in electroplating, and for electrodes in many electrolytic chemical processes.

In its chemical relations, graphite occupies a position distinct from that of any other form of carbon. The most striking difference is the effect of treatment with fuming nitric acid and potassium chlorate; diamond is unaltered, and amorphous carbon (charcoal) is completely dissolved, but graphite is converted into a compound known as graphitic acid or graphitic oxide ($C_{11}H_4O_5$).

As a fact of mineralogical interest, but one which has no industrial importance, it may be mentioned that meteoric masses have been found containing graphite which in its properties resembles the graphite formed during the cooling of high carbon and pig iron.

Occurrence and mining of crystalline graphite in the United States.—Crystalline graphite is widely distributed throughout the United States, but the known deposits of sufficient extent and purity to warrant working on a commercial scale are few in number. During the past decade the domestic output of high-grade crystalline graphite has been obtained chiefly from the mines near Ticonderoga, Essex county, N. Y. The mines in Chester county, Pa., were reopened in 1897, after a long period of inactivity, and have been in continuous operation since that time. In 1899 the mines in Clay county, Ala., produced a small amount. There has been considerable activity in the exploitation of graphite properties in Bartow county, Ga.; near Dillon, Beaverhead county, Mont.; in Merrimack county, N. H.; in McDowell county, N. C.; at Bloomington, in northern New Jersey; and in many localities in California; but up to the present time the work has been confined chiefly to determining the character and extent of the deposits, and to ascertaining by experiment the best method of concentrating the ore so as to convert it into a salable product. The limited number of graphite mines now producing the crystalline variety of the mineral bears witness to the difficulties encountered in the development of a prospect into a paying property.

The principal mines in New York are at Ticonderoga, Essex county. The graphite is of the foliated variety, occurring in minute scales in the cleavage planes of a seam of gray quartzite. The ore contains an average of 10 per cent of graphite, of which but little more than one-half is extracted by the prevailing method of working. The graphite-bearing bed lies between strata of massive micaceous gneiss, garnetiferous gneiss, and light-colored quartzite entirely free from graphite. The gneiss dips about 20° south. The graphite beds do not conform to this dip, but have a low pitch to the east. There are two mines in the same bed, on different sides of a fault. The graphite-bearing quartzite is from 1 to 5 feet thick in one mine, and from 2 to 15 feet thick in the other. This vein (known as the Hague vein) seems to have been in a line of weakness during the geologic upheavals, for the ore and wall rocks near the surface are very much pulverized, so that, while the ore carries a good percentage of graphite, the yield is small. It is probable that the deepening of the workings will result in finding the graphite in coarse flakes in the unaltered rocks, unless the faulting has occurred along the vein throughout its course. The mines are opened by adit levels, and the mined ore is treated for the separation of the graphite by crushing and washing in a mill near the mines, followed by a further refining at the works of the company at Ticonderoga.

There are numerous limestone deposits in Essex and neighboring counties of New York which contain graphite disseminated throughout the mass, or in small lenses of very rich ore. While a number of these deposits are being promoted and developed, the only ones of apparent promise are on Lead Hill, back of Ticonderoga, and on Warner Hill, between Ticonderoga and Crown Point. It is probable that if any more valuable mines are opened in this section they will be in the graphitic quartzite, as the lenticular bodies in the limestone have proved uncertain.

In Pennsylvania the principal graphite mine is 1 mile east of Chester Springs, Chester county. The mineral occurs in two layers of disintegrated mica schist, one 4 feet and the other 6 feet in thickness. Adit levels have been run in on the hillside, following the layers, and the rock is so disintegrated that most of the ore can be removed by pick and shovel without recourse to blasting. At the mill the ore is crushed in rolls and cleaned in a log washer of the type commonly used at clay works. After being washed it is again ground, refined by pneumatic concentration, and screened into different grades. There are other graphite properties in the state, notably at Byers, several miles below Chester Springs, and at Pikeland, both in Chester county, and also at Mertztown and Boyertown, Berks county. These properties have been productive at various times, but for the most part are now inoperative. The existence of graphite throughout a large part of the ridge extending from Phoenixville to the Brandywine river seems very probable. Occasionally pockets are found which yield nuggets and masses of nearly pure graphite, such as formed the basis of the producing mines in this region, but more often the mineral is associated with iron oxides, quartz, and feldspar, so that the extraction of the graphite involves considerable difficulty.

Concentrating crystalline graphite.—The increased demand for crystalline graphite has led to a careful study of the concentration of low-grade graphite disseminated in flakes. Operative plants have changed and improved their methods, and new concentrating processes are being tested.

There are two common methods of concentrating crystalline graphite from its ore—the wet and the dry. The wet or water method has been developed to a marked degree of efficiency, and is the one now generally used. The mode of procedure is to crush the ore wet, and separate coarsely by stationary buddles, the concentrates being dried and further treated with buhrstones and screens. No mill, however, has adopted either method in its entirety, because the specific gravities of the constituents of the ore vary so little. Several pneumatic processes have lately proved a partial success, but they have been of limited application, on account of the impossibility of removing the small scales of mica which occur in some of the deposits.

Two new features in concentration practice, in both of which the older method of complete submersion beneath the surface is replaced by flotation, are worthy of note—first, the use of petroleum vapor, which, being readily absorbed by graphite, permits the flakes to be more readily separated from the gangue material by flotation; and, second, the heating of the ground product before separation, which makes the flakes of graphite so light that they float on the surface of the water, whence they are removed.

Occurrence and mining of amorphous graphite in the United States.—Under this head are included also the graphitic anthracite of Rhode Island and the so-called Baraga graphite of Michigan. The incentive to develop properties containing amorphous graphite is much less than in the case of the crystalline variety. On account of the limited use of the former, the value of the crude product is only from one-eighth to one-tenth of that of the latter. For the manufacture of graphite crucibles and for many electrical purposes no satisfactory substitute for crystalline graphite has been discovered, while in the case of amorphous graphite there are many other materials of equal suitability for its various uses.

The mining of amorphous graphite in the United States has been of comparatively recent development. During 1902 the product was obtained chiefly from Wisconsin, followed by Michigan, Rhode Island, South Dakota, Wyoming, and New Mexico, in the order named. There are numerous deposits in other states, but none in sufficient quantity or purity to be of commercial value at the present time.

In Wisconsin, the mines near Stevens Point, Portage county, produce graphite which is reported to contain, at times, as much as 74 per cent of carbon. It is utilized in the manufacture of paint, lubricants, and greases.

In Michigan, there are several thousand acres in Baraga county, composed of a carbonaceous schist without a sign of a vein of graphite. This material is ground for paint and is improperly called graphite.

In Rhode Island, the mines near Cranston have been operated for many years. The graphite shows a structure between scaly and granular, and the grade of the product has not until recently exceeded 55 per cent of carbon, the remainder of the ore being silica and iron oxide, with a trace of sulphur. The property was originally a quarry, and in making the open cut the vein has been exposed for a distance of 70 feet or more. A shaft has been sunk, and most of the ore is now obtained from pockets, although it is found also in a few fissure veins.

In South Dakota, there are several graphite properties in the vicinity of Custer containing promising veins of graphite, one of which is reported to be 4 feet in width and of high-grade mineral. At Castle Creek, in Pennington county, 25 miles northwest of Custer, there is a vein which is reported to contain 40 per cent of carbon and to be in contact with a 10-foot layer of graphitized slate.

In New Mexico, considerable exploratory work has been done at the graphite properties 8 miles southwest of Raton, Colfax county.

Occurrence and mining of graphite in foreign countries.—In Ceylon, which is the chief producer of high-grade crystalline graphite, the main deposits are in the western and northwestern provinces. The graphite, which is scaly or fibrous in structure, is found in veins of irregular occurrence and extent, which break through crystalline rocks of the character of granulite. The minerals associated with graphite in the material which forms the vein are feldspar, rutile, pyrite, biotite, and calcite. The country rock is often highly decomposed, and then consists mainly of kaolin and similar decomposition products. The formation of graphite in these deposits has been attributed by Dr. Ernst Weinschenk to the decomposition of vapors carrying carbonic oxide and cyanogen compounds.

In one of the Ceylon mines near Caltura the graphite occurs in a series of veins in gneiss which has become converted, to a depth of 36 feet, into a mass resembling laterite. The indications point to the deposition of the carbon by the decomposition of hydrocarbon vapors, forming a true vein.

The Ceylon mining industry, which is entirely in the hands of the natives, has been profitable for many years, chiefly on account of the purity and consequent high value of the product. The method of mining is extremely primitive. A shaft is sunk to the level of the ground water (from 40 to 200 feet), and drifts are cut from the bottom of the shaft until the air is so bad that the lamps of the miners will no longer burn; the ground is then stoped upward, the waste being dropped behind until the shaft is filled. In some cases the veins are followed by open cuts and galleries. The underground workings are roughly timbered, and powder is used to break the rock. The ore is hoisted by windlass and bucket, or passed out by hand. A peculiar feature of the industry is the opposition to the installation of modern mining machinery and methods, on the ground that the new conditions might be less satisfactory than the older and fairly profitable ones. The mined product is famous for its purity, the analysis of several samples showing a carbon content of from 99.283 to 99.792 per cent.

In Austria, graphite occurs in the provinces of Bohemia, Styria, Moravia, Carinthia, and lower Austria. The chief producing mines are at Schwarzbach, in Bohemia. The deposits, which are lenticular, occur in gneiss, in parallel beds, extending over an area 14 miles long by 10 miles wide.

At Schwarzbach six beds have been exploited for a length of 1,800 feet and to a depth of 300 feet. The mines produce both hard and soft ore, the latter being graded into three classes. The first and second are hand picked, dried, and packed in barrels for the market; the third class and the hard mineral are crushed in water and dressed in tanks, the heavier impurities sinking to the bottom, while the slime, containing the graphite in a state of fine division, is collected in a filter press, and the resultant cakes, containing about 50 per cent of carbon, are dried and shipped to the market.

In Styria, which ranks second in importance, there is found a highly metamorphosed system of carboniferous shales, clay-slates, limestones, and conglomerates with coal seams, the coal of which has passed into graphite. It is very compact, very pure, and often extremely hard, in some cases retaining exactly the appearance of the coal from which it has been derived. The graphite region extends from Leoben to St. Lorenzen, a distance of 25 miles. The most important deposits are at St. Michael, where five parallel beds, varying in thick-

ness from a few inches to several feet, and occurring in grayish-black schist, have been exploited for a length of over 600 feet. The preparation for market consists in simple screening. The product, which contains nearly 80 per cent of carbon, is used in making graphite crucibles.

Other graphite deposits are found in lower Austria, Moravia, and Carinthia; but the mineral, which is associated with granular limestone in gneiss, and is usually amorphous and friable, is too impure to warrant working commercially.

The graphite deposits of Germany are confined to the easternmost corner of Bavaria. In a region bounded on the south by the Danube and on the east by the Austrian frontier are gneisses and gneissose rocks impregnated with scaly graphite. In some places—chiefly in the immediate neighborhood of intercalations of granular limestone, altered by contact metamorphism—the mineral occurs in lenticular masses, rich in carbon. Both the graphite-bearing rock and its near neighbors are highly decomposed, so that kaolin and other decomposition products are found in intimate association with the graphite deposits. The lenticular form of the deposits, their geological relationship with limestone intercalations, and their frequent association with kaolin and other decomposition products, connect them closely with the Bohemian type, from which they are differentiated by the less compact and more crystalline character of the graphite. The genetic connection between the Passau and Ceylon types is very close.

At Borrowdale, England, fine-scale graphite was at one time found in veins in "greenstone porphyry." The gangue material was chiefly calc-spar, brownspar, and quartz, containing nests and lumps of very fine graphite, especially suitable for the manufacture of pencils. These mines, however, have been exhausted.

The mines at Batugol, province of Irkutsk, Siberia, also are practically exhausted. The graphite was finely fibrous and purer than that at Borrowdale. The veins run through a granitic or dioritic rock, while in the closely adjoining limestone (altered by contact metamorphism) are great lumps of pure graphite, suitable only for pencils.

Artificial graphite.—Graphite can be made artificially in several ways, among which are the following:

(1) In the production of cast iron from ore containing a large proportion of carbon, by allowing the molten mass to cool slowly. As cast iron can retain in combination a much larger proportion of carbon when molten than when solid, the cooling of the mass causes the carbon to separate out, forming scales of graphite disseminated throughout the iron. It is to the presence of the scales of graphite that gray pig iron owes its peculiar properties and its gray color. When this form of pig iron is dissolved in acid, the scales of graphite remain as an insoluble residue. When cast iron is kept in a molten condition for a long time, as in the manufacture of converter steel, scales of graphite collect on the surface of the molten metal, forming so-called "kish." This source of artificial graphite is of no commercial importance.

(2) By the reaction or decomposition of various chemical compounds containing carbon, notably the cyanide class of salts. Graphite can not be produced commercially from chemicals on account of the excessively high cost.

(3) By the treatment of certain carbonaceous materials in the electric-arc furnace, which is the process now used on a very large scale.

Pure graphite has many valuable properties, such as high electrical conductivity, great resistance to chemical action, and absence of the property of absorbing gases, which is possessed more or less by all forms of amorphous carbon. Natural graphites of the high degree of purity required for delicate chemical and electrical processes are so expensive that in most cases the cost is prohibitive. The inception of the artificial graphite industry is due to the efforts and experiments of Mr. Edward G. Acheson,[1] who during 1897 manufactured more than 160,000 pounds of this product. In 1901 the output in the United States reached 2,500,000 pounds. At first the operations were confined to the graphitization of carbon electrodes, but since 1899 very large quantities of artificial graphite have been made, to be utilized for purposes for which natural graphite was formerly used. In graphitizing electrodes the ordinary electrode, which is composed of a mixture of petroleum, coke, pitch, and a carbide-forming material (silica or iron oxide), is subjected to the intense heat of an electric-arc furnace. The so-called "artificial graphite" is produced by subjecting anthracite coal, coke, or charcoal, together with a small proportion of some oxide or sulphate, to the intense heat of an electric-arc furnace; the impurities are eliminated, the ash being reduced in some cases to as low as five-tenths of 1 per cent.

The so-called artificial graphite, which is in the form of grains or powders, is used chiefly in the manufacture of paint, dry batteries, and commutator brushes, although a considerable quantity is used in the manufacture of lubricants for high-grade work, in electroplating, and in certain chemical processes which require a carbon of exceptional purity. Experiments have been made with this material as a coating for the grains of high explosives, to prevent the generation of the

[1] United States patents Nos. 645284, 645285, 701758, and 711031.

static charge of electricity, the spark from which is supposed to cause the spontaneous ignition of the powder.

Graphitized electrodes possess special qualities which render them valuable in electrolytic processes for the production of caustic soda and of chlorine and metals in chloride solution, and in electro-metallurgical processes, such as the production of calcium chloride, the electric smelting of copper and iron ores, and the manufacture of various iron alloys.

In spite of the development of artificial graphite, however, in recent years there has been a large increase in the demand for natural graphite, due to the growth of the iron and steel industries; the largely increased use of copper and its alloys; the development of electrical machinery, which calls for graphitized products; and the increased need for special lubricants to be used at comparatively high temperatures.

Uses of graphite.—Graphite is used for making refractory crucibles, stove polish, foundry facings, paint, and lead pencils; as a lubricant; and in powder glazing, electrotyping steam packing, etc.

For the making of crucibles crystalline graphite is required; the fibrous or laminated variety is used, because its superior binding qualities add to the strength of the crucible. The ordinary mixture consists of 50 per cent of graphite, from 35 to 45 per cent of air-dried clay, and from 5 to 15 per cent of sand. The graphite is ground to a fineness of from 40-mesh to 100-mesh size, according to the special use to which the crucible is to be put; if coarse it will give a porous crucible, while if too fine it will be apt to crack when heated, because of its great density. The clay is selected, not on account of its refractoriness, but because of its plasticity. The sand is free from fluxing impurities, such as iron oxide, lime, magnesia, etc., and is sifted through a 40-mesh screen.

In combining the constituents, the clay is made into a thin paste with water, and the graphite and sand are thoroughly mixed in by repeated treatments in an ordinary pug mill. The mass is kept moist for several weeks, in order to insure the expulsion of any air bubbles which may have been formed in the mixing. This stage of the work is called "tempering." A portion of the tempered mixture of the proper weight for a crucible of the desired size is molded into shape on an ordinary potter's wheel. This method is superior to machine molding, because the rotary motion and external pressure cause the flakes of graphite to become arranged nearly parallel to the sides of the molded shape, thus binding the mass together more strongly. The freshly-molded crucibles are inclosed for several hours in a close-fitting sectional mold of plaster, which absorbs a portion of the moisture; they are then dried for a week or ten days at a temperature of from 70° to 80° F., and finally are fired for several days in a common pottery kiln. The use for graphite crucibles of a fusible clay of great plasticity instead of one of high refractoriness is based upon the fact that for the combination of two substances by fusion mechanical contact is absolutely essential, so that, whether the clay be refractory or not, the presence of an inert material between the particles of clay and sand prevents fusion. Furthermore, as soon as the crucible is placed in the kiln the graphite on the outer surface is burned away by the oxidizing gases, permitting contact between the particles of clay and sand; these, reacting upon each other, fuse and form on the outside of the crucible a glaze which protects from oxidation the graphite flakes beneath the surface.

The quantity of the mineral used for making lead pencils is comparatively small, but the quality must be of the best. For use as a lubricant a high grade of the crystalline product is essential. But material of an inferior grade is employed in the manufacture of stove polish, of foundry facings, and of graphite paint, which is used to protect ironwork (as in smokestacks, iron roofs, elevated steel structures, etc.). While crystalline graphite is used to some extent, its special properties are not absolutely required, and hence the amorphous variety, both natural and artificial, is largely employed for these purposes.

TABLE 5.—DETAILED SUMMARY: 1902.

	United States.	New York.	All other states and territories.[1]
Number of mines	28	3	25

[1] Includes operators distributed as follows: Alabama, 1; Georgia, 2; Massachusetts, 1; Michigan, 2; Montana, 1 (8 mines); New Mexico, 1; North Carolina, 2; Pennsylvania, 2; Rhode Island, 1; South Dakota, 2; Wisconsin, 1 (2 mines); Wyoming (1 mine; operator reported in South Dakota).

LITHIUM ORE

LITHIUM ORE.

By Joseph Hyde Pratt.

The production of lithium ore has not been reported at any prior census, and there are, therefore, no comparative statistics available. The mining of lithium minerals for their lithia contents has been erratic in the United States, and it is only within the past few years that these minerals have been mined in any quantity. This is due to the small demand for lithium carbonate, which is the principal compound of lithium that is sold. The production for 1901 is stated by the United States Geological Survey to have been 1,750 tons, valued at $43,200. According to the same authority, 440 tons were mined in 1900 in San Diego county, Cal., and probably between 75 and 100 tons were obtained elsewhere for experimental purposes.

The following table is a summary of the industry for 1902:

Table 1.—*Summary: 1902.*

Number of mines or quarries	3
Number of operators	3
Salaried officials, clerks, etc.:	
Number	1
Salaries	$600
Wage-earners:	
Average number	6
Wages	$3,744
Miscellaneous expenses	$200
Cost of supplies and materials	$1,265
Product:	
Quantity, short tons	1,245
Value	$25,750

Detailed statistics by states can not be published without disclosing the business of individual establishments, 2 of which were located in California and 1 in South Dakota. One mine, in South Dakota, was idle. Of the 3 operators 2 were individuals and 1 was a firm.

Employees and wages.—Of the total amount, $4,344, paid in salaries and wages, $3,744, or 86.2 per cent, was paid to the wage-earners. There were 2 wage-earners on the average to a mine. The yearly average number of wage-earners employed was 6, the greatest average number, as shown by Table 2, being 23 for July and August, and the least, 5 for September. Four of the 6 miners, or 66.7 per cent of the total, received from $1.75 to $1.99 per day.

Production.—The production of lithium minerals in the United States during 1902 was 1,245 short tons, valued at $25,750. The world's annual production of lithium carbonate, which is the principal salt used, has been variously estimated at from 50,000 to 150,000 pounds. Most of this is manufactured in Germany, and a large proportion of the lithium minerals mined in the United States have been shipped to Germany, being returned in the form of lithium carbonate, quoted in New York at $1.35 per pound; the minerals are worth about $20 per ton f. o. b. at point of shipment. A small amount of ore has been treated at some of the chemical manufacturing plants in New Jersey, but thus far they have been unable to make it a profitable proposition. A company in New York, which controls the larger proportion of the deposits of lithium minerals in San Diego county, Cal., expects to erect a plant on the Pacific coast for the manufacture of lithium salts from their own ores.

If the estimate of 55,000 pounds of lithium salts, reported as the annual consumption in the United States, is correct, over one-third of this amount is imported. To produce this amount of lithium salts would require 371 tons of mineral containing at least 3 per cent of lithia (Li_2O); this indicates the relatively small amount of lithium minerals required to supply the home consumption of lithium salts.

Occurrence and uses.—The minerals which have been sources of lithium salts are lepidolite and spodumene, which contain from 4 to 7.6 per cent of lithia (Li_2O). There is another mineral, amblygonite, which has recently been found in quantity and will very probably be mined as a source of lithium salts. The first two minerals are silicates of aluminum and lithium, while the amblygonite is a phosphate of aluminum and lithium with varying percentages of the other alkalies.

Lepidolite has been the chief source of lithia, although theoretically spodumene contains a considerably higher percentage of lithia. Two of the mines in 1902 produced lepidolite and 1 spodumene, the value of the lepidolite constituting over 70 per cent of the total value of the product shown.

The principal occurrences of lepidolite in the United States are in the vicinity of Pala, San Diego county, Cal. Although it has been known for some years that

lepidolite deposits occurred there, it was not until about 1899 that any special work began, and regular shipments were not made until the following year. Lepidolite has also been found in some quantity at Hebron, Auburn, Rumford, and Paris, Me., but thus far no work has been done especially for this mineral at any of these places. The mining has been confined to tourmaline, which is found associated with it. In some cases the lepidolite has been separated and a few barrels shipped.

Spodumene has been found in quantity at Branchville, Conn., where it occurs in a pegmatitic dike in crystals, often of very large size, and in the Black Hills of South Dakota. The latter locality is the most noted one commercially and is probably the only one from which spodumene has been shipped as a source of lithium salts. In South Dakota the mineral occurs in pegmatitic dikes, which were formerly worked for tin.

The only locality where amblygonite has been reported to occur in sufficient quantity to make it a possible commercial source of lithium salts is near Pala, Cal., where it has been found associated with lepidolite.

Although only a few large deposits of these lithium minerals are known in the United States, it is not at all improbable that if the demand for them should increase to any considerable extent other deposits in quantity would be found; but, on account of the present comparatively small demand for the minerals, there is now practically no incentive for investigation.

The demand for lithium minerals is not large, for the reason that the uses of the salts of lithium are very limited; it is these salts that are used in the arts, and not the metal itself. The principal use of the salts is in the preparation of mineral waters and effervescing lithia tablets used for medicinal purposes. Another use that might be made of lithium carbonate and of lithium nitrate, if the price could be reduced sufficiently, is in pyrotechnics for red fire, for which purposes strontium salts are now used.

The following table is a detailed summary of the lithium industry for 1902:

TABLE 2.—*Detailed summary: 1902.*

Number of mines or quarries	3
Number of operators	[1]3
Character of ownership:	
Individual	2
Firm	1
Salaried officials, clerks, etc. (superintendents):	
Number	1
Salaries	$600
Wage-earners (miners or quarrymen):	
Average number	6
Wages	$3,744
Average number of wage-earners at specified daily rates of pay (miners or quarrymen):	
$1 to $1.24	1
$1.75 to $1.99	4
$3.25 to $3.49	1
Average number of wage-earners employed during each month:	
Men 16 years and over—	
June	21
July	23
August	23
September	5
Miscellaneous expenses:	
Total (rent of offices, taxes, insurance, interest, etc.)	$200
Cost of supplies and materials	$1,265
Product:	
Quantity, short tons	1,245
Value	$25,750

[1] Includes 2 operators in California and 1 in South Dakota.

MARL

MARL.

By Story B. Ladd.

The statistics of marl presented herewith relate to the marl product mined and used as a fertilizer, and are confined to the greensand deposits found in New Jersey, Delaware, Maryland, and Virginia. At the Tenth Census no statistics in regard to marl were published. At the Eleventh Census the total production of marl in the United States for the year 1889, was 139,522 short tons, valued at $63,956. The production was limited to five states, viz, New Jersey, Virginia, North Carolina, Alabama, and Arkansas. In four of the states the production was very small, New Jersey alone producing 99 per cent of the total.

During the period 1889 to 1902 there was a very extensive development in the manufacture of Portland cement from the marls of Michigan, Indiana, Ohio, and New York, in the lake region, resulting in a consumption of over a million cubic yards of the material, but as this was all manufactured into cement it is considered in connection with the statistics for cement.

Table 1 is a summary of the statistics for the marl industry as reported for the year 1902:

Table 1.—*Summary: 1902.*

Number of mines or quarries	11
Number of operators	11
Salaried officials, clerks, etc.:	
Number	2
Salaries	$2,100
Wage-earners:	
Average number	13
Wages	$4,769
Miscellaneous expenses	$1,407
Cost of supplies and materials	$2,755
Product:	
Quantity, short tons	12,439
Value	$12,741

Of the 11 mines or quarries for which production was reported, 10 were in New Jersey and 1 was in Virginia. The Virginia mine was in Prince George county and the New Jersey mines were distributed as follows: 1 in Burlington county, 1 in Gloucester county, and 8 in Monmouth county. One hundred and four properties reported to the United States Geological Survey as in operation in 1901 were idle during 1902. All of these were in the state of New Jersey, and were distributed as follows: Burlington county, 52; Camden county, 1; Gloucester county, 2; Monmouth county, 48; and Salem county, 1. As but 1 producer outside the state of New Jersey reported in 1902, the statistics are presented for the United States as a whole.

Capital stock of incorporated companies.—Of the 11 producers, 2 were incorporated companies—1 in New Jersey and 1 in Virginia—but neither was engaged exclusively in mining. Their authorized capitalization consisted of 5,380 shares of common stock, of a par value of $67,300. All of the stock was issued but no dividends were paid on it.

Employees and wages.—But 1 producer reported salaried employees; these were 1 superintendent and 1 clerk. The small number of wage-earners employed—13 by the 11 producers—shows that the work was done largely by the owners themselves. The work is all above ground, being mere excavation. Only one establishment reported the employment of power, with 2 employees classed under "engineers, firemen, and other mechanics." Of the total amount, $6,869, paid for salaries and wages by the 11 producers, the sum of $4,769, or 69.4 per cent, was paid to the 13 wage-earners, and $2,100, or 30.6 per cent, to the 2 salaried employees.

The variation in the number of wage-earners employed at different seasons of the year is shown by Table 3, which gives the average number of men and boys, respectively, employed during each month. The small number of wage-earners reported for each month will not warrant any deductions. It may be said, however, that more laborers find employment late in the autumn and early in the spring, when the farming operations of the proprietors are practically suspended. Thus the range in 1902 was from 10 wage-earners during January and February and during the summer to 17 in November.

In addition to asking the average number of employees and the total amount paid as wages, the schedule called for the number of wage-earners employed at the specified daily rates of pay, and these statistics are also shown in Table 3. The excavation of marl requires no skill and the rates of pay should not be compared with those paid in other mining industries requiring skill and experience. Thirty-eight and four-tenths per cent received less than $1 per day; 30.8 per cent, from $1 to $1.24; and 30.8 per cent, from $1.50 to $1.74.

Supplies, materials, and miscellaneous expenses.—The total amount expended for supplies and materials was $2,755. Most of this is chargeable against 4,267 tons of marl dried and ground. The amounts chargeable against the 8,172 tons of crude marl reported is less than 3 cents per ton. The total amount reported for miscellaneous expenses, $1,407, is also for the most part expense chargeable to the treated product. It was paid for "rent of offices, taxes, insurance, interest,

and other sundries," and no expense was reported for "royalties and rent of mine and mining plant." Of the 11 producers, 7 reported no expense for supplies and materials, and 8, no miscellaneous expenses.

Production.—The United States Geological Survey publishes statistics concerning the quantity and value of the marl product of the country produced each year, and Table 2 shows the totals for each year since 1880 and the average price per ton.

TABLE 2.—*Production of marl: 1880 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

YEAR.	Quantity (short tons).	Value.	Average value per ton.
1880	1,000,000	$500,000	$0.50
1881	1,000,000	500,000	0.50
1882	1,080,000	540,000	0.50
1883	972,000	486,000	0.50
1884	875,000	437,500	0.50
1885	875,000	437,500	0.50
1886	800,000	400,000	0.50
1887	600,000	300,000	0.50
1888	300,000	150,000	0.50
1889	139,522	63,956	0.46
1890	153,620	69,880	0.45
1891	135,000	67,500	0.50
1892	125,000	65,000	0.52
1893	75,000	40,000	0.53
1894	75,000	40,000	0.53
1895	60,000	30,000	0.50
1896	60,000	30,000	0.50
1897	60,000	30,000	0.50
1898	60,000	30,000	0.50
1899	60,000	30,000	0.50
1900	60,000	30,000	0.50
1901	[1] 99,880	124,880	1.25
1902	[1] 12,439	12,741	1.02

[1] Includes crude and manufactured products.

The production for 1902 was 12,439 tons, valued at $12,741. Crude marl contributed 8,172 short tons, and the remaining 4,267 tons were treated by drying and grinding. The former was valued at $4,865 and the latter at $7,876. This shows an average value of $1.02 per ton for both crude and treated marl. The average value per ton for crude marl used as a fertilizer without previous treatment was $0.595; the average for the treated product was $1.845.

The detailed statistics of the marl industry for 1902 are given in Table 3.

DESCRIPTIVE.

Marl in a general sense is a mixture of calcium carbonate and clay, occurring naturally with more or less siliceous sand. It is sometimes compact and sometimes pulverulent, and there is a wide range in the character of the material to which the term is applied in different localities. The term "greensand" is given to marl having a green color, because of the presence of grains of green silicate of iron. Most of the varieties of marl found in the United States conform to the general definition, and have calcium carbonate as their principal constituent. The cretaceous marls of New Jersey, as a rule, contain lime in small and variable amounts, and also considerable potash and phosphoric acid. The fertilizing value is due chiefly to these last two constituents. Potash constitutes from 3.5 per cent to 7 per cent, and phosphoric acid from 1.25 per cent to 9 per cent of the whole. The marls of New Jersey have long been used; in some years very extensively.

Marl improves both the chemical and physical conditions of the soil, neutralizing acidity, making available plant food otherwise insoluble, and promoting nitrification. It is very lasting in its effects, and has been used from ancient times for restoring worn-out and improving barren lands. On account of its bulkiness and the large amounts required to secure beneficial results, marl can be used profitably only in close proximity to the deposits. Mr. James C. Booth, in a report of the geological survey of Delaware for 1841, recommends the use of from 60 to 100 bushels per acre on light soils and from 100 to 200 bushels on clay soils, and states that from 200 to 500 bushels may be used on soils of good quality abundantly supplied with humus. The addition of 10 per cent of quicklime to the marl quickens its action.

MICA

MICA.

By Joseph Hyde Pratt.

The mica industry has probably seen as much variation in value and quantity of product as any other of the nonmetallic mineral industries.

In Table 1 is given a comparative summary of the statistics from 1870 to 1902.

Table 1.—*Comparative summary: 1870 to 1902.*

	1902	1889	1880	1870
Number of mines	49	4	22	(1)

Cost of supplies and materials	$11,961	$7,408	$6,110	$85
Value of product	$118,849	$52,450	$127,825	$7,000

[1] Not reported. [2] Establishment. [3] Not reported separately.

The 49 mines reported in operation during 1902 were located in the following states: North Carolina, 28; California, 10; South Dakota, 3; Maine, 2; New Hampshire, 2; Virginia, 2; Georgia, 1; and New Mexico, 1. Of the 38 operators, 26 were in North Carolina, 3 in South Dakota, 2 each in Maine, New Hampshire, and Virginia, and 1 each in California, Georgia, and New Mexico. Of these operators, 18 were individuals, 11 were firms, and 9 were incorporated companies. North Carolina was the main producer of mica in the United States; in 1902 the value of its production was 59.8 per cent of the total.

The total amount of salaries and wages paid in 1902 was $15,313 more than the amount reported for 1889 and $8,113 less than at the census of 1880. The production reported in 1902 was 373,266 pounds of cut or sheet, 1,028 short tons of scrap or waste, and 372 short tons rough as mined. This production of sheet mica is about five times that reported in 1880 and nearly eight times that for 1889; but the total value, $118,849, of all the mica produced in 1902, although much more than that shown for 1870, is $8,976 less than the value of the production reported at the census of 1880. This is due in part to the somewhat higher prices received in 1880, and also to the very large quantity of small disks and sheets cut in 1902 for electrical purposes.

The decrease of $75,375 in value between 1880 and 1889 reflects the decrease in production and fall in price caused by the large amount of mica imported from India. The reporting of 196 tons of scrap or waste in 1889 indicates the beginning of the use of mica in the manufacture of wall papers, lubricants, etc.

The principal changes in the mica industry, since the census of 1890, have resulted from the utilization of the scrap mica, which was formerly thrown away as valueless, and the cutting of large quantities of small disks, 1 inch in diameter, and small sheets 1 by 1½ inches and 1 by 2 inches, for electrical purposes. This waste having become of value it is possible to work properties which would otherwise be unprofitable. Many new uses for both sheet and scrap mica have been devised during the past few years, so that although there has been a very large falling off in the amount of sheet used in stoves (which was formerly the principal use of mica) the quantity of all mica used has greatly increased.

The mines that were idle in 1902 number 36, of which 14 were in North Carolina, 5 each in New Hampshire and Idaho, 3 in New Mexico, 2 each in Alabama and South Dakota, and 1 each in Georgia, Nevada, Ohio, Pennsylvania, and Vermont. They were owned by 34 operators, of whom 21 were individuals, 7 were firms, 5 were incorporated companies, and 1 was a cooperative association. The authorized capital stock of the 5 incorporated companies was $1,100,000, of which shares to the value of $229,500 were issued. The assessment levied amounted to $1,600.

Capital stock of incorporated companies.—Table 2 gives the details of the capitalization of the 9 incorporated companies operating productive mines.

Table 2.—*Capitalization of incorporated companies: 1902.*

	United States.	North Carolina.	South Dakota.	All other states.[1]
Number of incorporated companies	9	3	2	4
Number reporting capitalization	8	2	2	4
Capital stock (all common):				
Total authorized—				
Number of shares	5,302,000	501,000	3,500,000	1,301,000
Par value	$5,450,000	$550,000	$3,500,000	$1,400,000
Total issued—				
Number of shares	3,150,348	50,100	1,908,248	1,192,000
Par value	$3,254,248	$55,000	$1,908,248	$1,291,000

[1] Includes companies distributed as follows: California, 1; Georgia, 1; Maine, 1; New Hampshire, 1.

Of the authorized capital stock, all of which was common, 59.7 per cent had been issued. South Dakota reported 64.2 per cent of the whole amount authorized and 58.6 per cent of the amount issued.

Employees and wages.—The total number of employees reported for the mica industry in 1902 was 119, comprising 21 salaried employees and an average during the year of 98 wage-earners. They received in salaries and wages $57,487, of which amount $13,444, or 23.4 per cent, was paid out in salaries and $44,043, or 76.6 per cent, was paid out in wages.

The month in which the greatest number of wage-earners was engaged, as shown in Table 6, was August, when the number amounted to 112; the lowest was in January, with 75. The falling off during the winter months of January, February, and March was in "all other states." It is interesting to note that there were no wage-earners under 16 years of age employed.

The average number of wage-earners at specified daily rates of pay is also given in Table 6. The wages received varied from 75 cents to $3.74 per day, the most usual rate, however, being from $1 to $1.24. There were 62 wage-earners whose wages were less than $1.25 per day, and of these 49 were classified as miners. These low wages are accounted for by the fact that most of the mining was carried on in North Carolina, where there is a low scale of wages. The miners in the Western states command higher wages as indicated by the fact that the 12 miners who were reported to have received from $2.50 to $2.74 per day were employed in western mines.

Of the 98 wage-earners, 81 worked above ground and only 17 below ground, indicating that most of the mica mining was done in shallow pits and cuts. It was not extensive enough to require much underground work. The number of wage-earners classified as miners was 70. Of these 58 worked above ground and 12 below ground. One foreman was reported employed below ground; therefore, the total number of underground miners was 13, and of underground employees 18.

Supplies, materials, and miscellaneous expenses.—The total cost of supplies and materials and miscellaneous expenses, reported at the census of 1902 for the mica mining industry was $24,875, of which $11,961 was paid for supplies and materials required in mining the mica; $3,142 for roy .lties and rent of mines and mining plants; and $9,772 for rent of offices, taxes, insurance, and other sundries.

Mechanical power.—The total horsepower utilized in the mica industry was 201, generated by 8 steam engines with 160 horsepower; 1 gasoline engine with 25 horsepower; and 1 electric motor of 16 horsepower. Of this amount, only 10 horsepower, generated by 1 steam engine, was used in North Carolina.

Production.—The production of mica in 1902 consisted of 373,266 pounds of cut, sheet, or plate, valued at $83,843; of 1,028 short tons of scrap or waste, valued at $13,081; and 372 tons rough as mined, valued at $21,925, making the value of the total production $118,849. The 372 tons of mica rough as mined would yield approximately 150,000 pounds of cut, leaving 297 tons of scrap.

The large increase in the production of sheet mica during the past few years has been accompanied by a large decrease in the production of scrap mica. This decrease is accounted for by the fact that most of the scrap mica now produced is that obtained as waste in the present mining or cutting of the sheet mica, where formerly a very large percentage put on the market was obtained from old dumps from former mining. In the following table is shown the annual production of mica in the United States since 1889, these figures having been published by the United States Geological Survey:

TABLE 3.—*Production of mica: 1889 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

YEAR.	Total value.	CUT OR SHEET.		SCRAP OR WASTE.		ROUGH AS MINED.

[1] Including mica waste.

On July 24, 1897, a new classification of imports of mica was adopted, showing "unmanufactured" and "cut or trimmed." The imports are given in Table 5.

TABLE 5.—*Mica imported and entered for consumption: 1897 to 1902.*

YEAR.	Quantity (pounds).	Value.	YEAR.	Quantity (pounds).	Value.
1897.			1900.		
Prior to July 24....	656,118	$140,353	Unmanufactured.	1,892,000	$290,872
After July 24:			Cut or trimmed...	64,391	28,688
Unmanufactured	66,821	10,981			
Cut or trimmed..	226,771	41,068	Total	1,956,391	319,560
Total	949,710	192,402	1901.		
1898.			Unmanufactured.	1,598,722	299,065
			Cut or trimmed...	78,843	35,989
Unmanufactured..	877,930	115,930			
Cut or trimmed....	78,567	34,152	Total	1,677,565	335,054
Total	956,497	150,082	1902.		
1899.			Unmanufactured.	2,149,557	419,362
			Cut or trimmed...	102,299	46,970
Unmanufactured..	1,709,839	233,446			
Cut or trimmed....	67,293	42,538	Total	2,251,856	466,332
Total	1,777,132	275,984			

As is shown in the above table, the imports for mica for 1902 amounted to 2,251,856 pounds, valued at $466,332, which is an increase over the importation of 1901 of 574,291 pounds, valued at $131,278. The main point to be noticed, however, is that this increase is greater than the total value of the production of mica in the United States during 1902, showing that the increasing demand for mica in this country is being supplied largely by foreign countries.

The relatively small production of mica in the United States as compared with the importation can be accounted for partially by the low prices maintained for plate mica, by the uncertainty of the occurrence of mica in the veins, and by the large number of small producers each depending upon one small mine. When the mica in the mines of these small producers begins to give out or becomes poor, they do not have the means to carry the necessary amount of "dead" work. The importation of mica from Canada and India at a low valuation tends also to curtail the production of mica in the United States because of the influence it has on the prices of the mica produced at home. This is especially true of the mica imported from India, which can be mined and landed in this country at a price lower than the cost of production at some of the mines in the United States.

The detailed statistics of the industry for 1902 are given in Table 6.

DESCRIPTIVE.

Occurrence and use.—Mica, in some form or other, is probably familiar to everybody because it is so very widely distributed in nature, being a component part of many of the crystalline and sedimentary rocks. Its commercial value is dependent upon its occurrence in blocks or masses that are capable of being split into sheets a square inch or more in size. Deposits of commercial mica occur for the most part in pegmatitic dikes or veins which are found in granite and hornblende and mica gneisses or schists. These dikes or veins vary in thickness from a few inches to several hundred feet and are often very irregular, having arms or veinlets branching off in many directions. In character, these dikes are similar to granite, and sometimes they are called "coarse granite," and if we could conceive of the constituents of granite being magnified a hundred times or more we would have an appearance similar to a pegmatitic dike.

The mica in these pegmatitic dikes will seldom average over 10 per cent of the contents of the dike and sometimes will be as low as 1 per cent. Often a dike will have the appearance of containing a very high percentage of mica on account of a number of blocks being clustered together in bunches almost touching each other, while in another portion of this same dike the mica will be almost entirely absent for a distance of from 5 to 20 feet; thus the general average of mica in the dike will be from 1 to 10 per cent only. Of the mica obtained from these dikes, usually only from 5 to 25 per cent can be cut into sheet or plate mica. The average is probably about 10 per cent. Occasionally large quantities of mica are mined in which there is not over 1 per cent that can be made into sheet mica. These commercial occurrences of mica are not very abundantly distributed throughout the United States, although rocks in which mica is one of the chief constituents are very common. At the present time deposits of commercial value are known to occur in Alabama, Arizona, California, Colorado, Connecticut, Georgia, Idaho, Maine, Missouri, Nevada, New Hampshire, New Mexico, New York, North Carolina, Rhode Island, South Carolina, South Dakota, Vermont, Virginia, and Wyoming; and in Arkansas there are also deposits which may become of commercial importance. In most of these states the deposits were not worked in 1902. In some of them the deposits were not available on account of their distance from railroads, this being especially true of those in Arizona, Colorado, Nevada, New Mexico, and Wyoming. In others little has been done owing to the uncertainty of the price and the demand. Many of the deposits of Maine have only recently been opened, and therefore have not been extensively developed.

Mica was first produced in the Eastern states along the Appalachian mountains, and twenty years ago mining was carried on vigorously in Connecticut, New Hampshire, North Carolina, and Virginia. In the eastern field the principal mining is in North Carolina, which, since the beginning of the mica industry in the United States, has been the chief producer of the mineral. At just what time the first work was done on the mica deposits of North Carolina is uncertain, and since there

is no record of the old mining and none of the inhabitants of this section have any information whatever regarding these old workings, they have been attributed to the Indians. Trees 2 feet and over in diameter have been observed growing from these cuts. Stone implements have been found in some of the old tunnels, indicating the antiquity of these workings. Most of these old mines are located in Mitchell and Yancey counties.

Of the North Central states, South Dakota has been and still is the state in which the largest quantity of mica is produced; while of the Western states and territories, New Mexico has for a number of years been the largest producer, but is now likely to have to give way to California. These California deposits have only been opened up within the past few years, but the mining is now being carried on quite extensively. At the present time the Nevada deposits are too isolated to warrant mining on an extensive scale. The completion, however, of the railroad, which is being constructed from California across Nevada and Arizona to Utah, will make these deposits more available for commercial purposes.

The uses of mica are somewhat varied; there are two forms in which it is used, (1) sheet or plate mica and (2) scrap mica.

Sheet or plate mica.—Mica is cut into sheets of various sizes which are used for stoves, lamp chimneys, incandescent lights, and in electrical apparatus for insulation purposes. While the use of this sheet mica for stoves has decreased very rapidly during the past ten years, there has been a corresponding increase in its use for electrical apparatus. It is also used in place of glass in the manufacture of a great many novelties and in many respects increases the usefulness of the articles made. There was formerly a considerable demand for the larger sheets of mica, but these have been replaced to some extent at the present time by a manufactured product known as micanite, which is made from very small, perfect pieces of mica rearranged and cemented together into larger sheets. For some purposes these manufactured sheets are as satisfactory as the natural ones and are, of course, much cheaper.

The value of sheet or plate mica varies with the size of the sheet and is from 2 cents to $3 per pound. The values of from 2 to 5 cents per pound are for the small disks and rectangular sheets that are cut by machinery and are used extensively in electrical apparatus. The larger sheets are cut by hand and considerable skill is required to cut the largest pattern possible from the crude block of mica.

Scrap mica.—The waste or scrap mica not suitable for cutting into sheets of even the smallest size has a value when ground to a flour, which is used in the manufacture of wall papers, lubricants, fireproofing material, artificial snow, novelties, etc. Coverings for boiler tubes and steam pipes are also manufactured from particles of scrap mica which are not ground but are broken into pieces of approximately the same general dimensions, one-half by one-fourth of an inch. These are then arranged with their longer dimension and face parallel to the length of a wire net coil, pressed into the shape of a pipe or tube, against which the layer of scrap mica is kept tightly in place by means of heavy canvas. A number of the states, especially North Carolina, offer very favorable locations for the erection of plants to manufacture products from scrap mica, as there is usually a supply of available water-power near the deposits.

The commercial value of scrap mica before it is ground is from $8 to $10 per ton, delivered at the railroad, and it is this value that has made it possible to work some of the mines that otherwise would have been shut down, for in some cases this waste mica represents from 75 to 95 per cent of the mica mined. After being ground, the mica is worth from $40 to $60 per ton, according to its mesh.

There are a number of minerals, especially quartz and feldspar, associated with the mica, which in some instances should prove of considerable commercial value as by-products in mining the mica, provided water-power for grinding these minerals can be secured near the source of supply. Occasionally some of the gem minerals, as beryl and tourmaline, are found associated with the mica, and furnish some very handsome cut stones. Some of the pegmatitic mica-bearing dikes are rich in the variety of minerals that they contain, while others have very few besides those typical of a pegmatitic dike. Between forty-five and fifty different minerals have been found associated with mica at the different mines throughout the country.

The small production of mica in the United States as compared with the importation is not due to a deficiency in the supply of the mineral in this country. It is undoubtedly true that in the Appalachian region, especially in the southern area, there are many good deposits of mica yet to be discovered which will yield as rich returns as many of those that have already been mined. It is also true that many of the mines that were worked so extensively twenty years ago, especially those in North Carolina, still contain good deposits of mica which the former owners were prevented from taking out on account of the presence of water, which they were unable to control with the means that they had at hand. Any increase in the duty on mica or any considerable decrease in the importation of mica from India and Canada would cause an increase in the price of mica, and would result undoubtedly in a large and immediate increase in its production in the United States.

MONAZITE

MONAZITE.

By Joseph Hyde Pratt.

There is no mention of the monazite industry in any previous census report, for the reason that the production of this mineral for commercial purposes did not really begin until 1893. As early as 1879 the existence of monazite in commercial quantities in North Carolina was proved by W. E. Hidden, but it was not until 1887 that the first shipment was made. During that year 12 tons of monazite sand from the Brindletown district, in Burke county, N. C., were shipped for experimental purposes, and in the following two years, 1888 and 1889, a few tons were shipped to a northern company. The statistics for 1902 are summarized in the following table:

Table 1.—*Summary: 1902.*

Number of mines	23
Number of operators	22
Salaried officials, clerks, etc.:	
Number	3
Salaries	$2,100
Wage-earners:	
Average number	88
Wages	$25,318
Miscellaneous expenses	$2,083
Cost of supplies and materials	$256
Product:	
Quantity, pounds	802,000
Value	$64,160

One mine in North Carolina was reported idle during 1902. The industry is one of placer mining and is irregularly carried on in many instances, the expenses of some of the producers being advanced by the operators of a concentrating plant. It was deemed inadvisable to obtain separate statistics for these three or four hundred small and irregular miners. Over half the quantity of monazite produced during 1902 is credited to them. This is accounted for in the report of the concentrating plant which purchased the mineral, the miners selling monazite to such plant being included in its return as employees engaged in mining by the pound, and the total amount paid for the mineral being given as their wages. The number of these irregular contract miners was reduced to 65—the number computed to have been working 300 days during the year—and is included in the statistics here presented.

The number of placer deposits or mines for which statistics were received at the census of 1902 was 23. Of the 22 operators working these mines, 20 were individuals, 1 was a firm, and 1 an incorporated company. The incorporated company had a total authorized capital stock of $500,000, divided into 10,000 shares, of which 20 shares, with a total par value of $1,000, had been issued.

Employees and wages.—Of the total amount, $27,418, reported as paid for salaries and wages, $25,318, or 92.3 per cent, was paid to the wage-earners and $2,100, or 7.7 per cent, to the salaried employees. On an average, there were 3.8 wage-earners to a mine. The average number of wage-earners by months and their daily rates of pay by occupations are given in Table 3. The maximum, 130, was reached in August and the minimum, 20, in November and December. Of the 88 wage-earners, 86 were classed as miners. Of these, 73 received from $1 to $1.24 per day, and 13 from 75 to 99 cents.

Supplies, materials, and miscellaneous expenses.—Only $256 were reported to have been expended for supplies and materials. Next to the amount paid for wages that for miscellaneous expenses, $2,083, is the largest. Of this $1,739, or 83.5 per cent, was paid for royalties and rent of mine and mining plant.

Mechanical power.—Of the 22 operators only 1 reported power. This was a firm in North Carolina, which owned 2 steam engines with a total of 30 horsepower.

Production.—The United States Geological Survey has published annual statistics of the production of monazite, beginning with 1893. These statistics, together with the average value per pound, are shown for each year in the following table:

Table 2.—*Production of monazite: 1893 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

Year.	Quantity (pounds).	Value.	Average value per pound.
1893	130,000	$7,600	$0.058
1894	546,855	36,193	0.066
1895	1,573,000	137,150	0.087
1896	30,000	1,500	0.05
1897	44,000	1,980	0.045
1898	250,776	13,542	0.054
1899	350,000	20,000	0.057
1900	908,000	48,805	0.054
1901	748,736	59,262	0.079
1902	802,000	64,160	0.08

The total quantity produced during the ten years was 5,383,367 pounds, an average of 538,337 pounds per

year. By far the largest quantity was produced in 1895, the next largest in 1900, and the third largest in 1902. The average price during the ten years was 7¼ cents per pound.

The value of monazite has varied from 25 cents per pound, the price received for the production of 1887, to 3 cents per pound received for the less pure sand sold by the small producers who were able to eliminate only a small percentage of the heavy minerals. At the present time the sand mined by the small producer is sold to the concentrators and is paid for on the basis of its value after it has been concentrated as thoroughly as possible, so that during the past year or two the price reported by these small producers has increased from 4 cents per pound for crude sand to 8 or 9 cents per pound for the refined product.

The entire production reported at the census of 1902 is credited to North Carolina. Since the beginning of the industry monazite has been produced chiefly in North Carolina, although at first a considerable quantity was obtained from Spartanburg county, South Carolina.

The production of monazite in commercial quantities became a well established industry in 1893, the output for that year being 130,000 pounds, valued at $7,600; during the next two years the production increased very rapidly, until, in 1895, it amounted to 1,573,000 pounds, valued at $137,150, or about 9 cents per pound. It was at this time that the Brazilian deposits of monazite, which occur in large quantity as beach sands along the seashore in the extreme southern part of the province of Bahia, began to be worked on a considerable scale; the production in the United States was affected thereby to such an extent that by the end of 1896 it had decreased to 30,000 pounds. In 1898 there was again a considerable demand for North Carolina monazite, and the production amounted in that year to 250,776 pounds, valued at $13,542. Since that time the production of this mineral has increased, and at the census of 1902 it was 802,000 pounds, valued at $64,160. It sometimes happens that while the quantity of monazite sand produced in a particular year is more than that for the year following, the value of the production of the latter year is considerably more than that of the former, because of the higher percentage of monazite obtained by a more thorough cleaning of the sand.

The monazite industry is steadily increasing, and there is now a considerable demand for this mineral, not only in this country but also abroad. During 1902 a German company was organized and bought up monazite lands in North Carolina. This company has erected the most complete concentrating plant in the district. Its production is to be shipped abroad.

DESCRIPTIVE.

Occurrence.—The commercial deposits of monazite do not occur in the original rocks, which are granitic mica gneisses and hornblende gneisses, and contain only a fraction of a per cent of this mineral; they are found in the placers of the present streams and rivers, and in the old sand and gravel deposits of former streams. As these gneisses are constantly being decomposed and disintegrated, the monazite is continually being washed down and deposited so that in many cases the top soils form workable deposits for monazite sand. The area in which these deposits are located is in Burke, Cleveland, McDowell, Polk, and Rutherford counties, N. C., and in the northern part of Spartanburg and York counties, S. C. They are found along the following streams: Silver, South Muddy, and North Muddy creeks, and Henry and Jacob forks of the Catawba river, in Burke and McDowell counties; the Second Broad river and its tributaries in McDowell and Rutherford counties; and the Broad river and its tributaries in Cleveland and Rutherford counties, N. C., and Spartanburg and York counties, S. C. All these streams have their sources in the South mountains of North Carolina.

Process of cleaning.—The value of monazite sand is dependent principally upon the oxide of thorium, and to a less extent on the oxides of cerium, lanthanum, and didymium. As the thorium oxide or thoria contents are due to the presence of the mineral monazite, the nearer to a pure monazite that the sand can be cleaned, the higher the percentage of thoria. Formerly a sand containing from 65 to 70 per cent of monazite was considered of very good quality; now, with improved machinery and new methods a sand can be obtained that is over 95 per cent monazite. In washing the sands, the lighter material is readily floated off, but magnetite, menaccanite (or ilmenite), rutile, brookite, garnet, zircon, etc., remain with the monazite. The magnetic minerals, such as magnetite and menaccanite are then removed. Formerly the other minerals could be only partially eliminated, but now, with the improved electro-magnetic separator, the other iron minerals are readily picked out; the final operation is the picking up of the monazite grains, leaving the zircon, corundum, etc. In this way an almost pure monazite concentrate is obtained.

Uses.—The principal use of the oxides of thorium, lanthanum, and didymium is in the manufacture of the cylindrical hoods of the Welsbach and other incandescent gas lights. Small quantities of the cerium oxalate obtained during the process of separating the other oxides are used in pharmacy.

Table 3 is a detailed summary of the monazite industry for 1902.

PRECIOUS STONES.

By George F. Kunz.

In the United States precious stones have been generally found by accident; in prospecting for, operating, or developing mines of other minerals; or in the working of gravels containing gold, monazite, etc. With the exception of the figures relating to the number of operators and the value of production, the statistics herewith presented are for properties operated by companies which carry on the search for stones with some approach to regularity. These companies produce sapphire, tourmaline, beryl, chrysoprase, opal, and turquoise. In addition to these, certain quantities of emerald, peridot, several varieties of quartz, such as rock crystal, smoky, rose, gold, and rutilated quartz, amethyst, agate and moss agate, and silicified wood; also garnet (pyrope and rhodonite), amazon stone, chlorastrolite, mesolite, pyrite, anthracite, and catlinite, were produced in this country during 1902, but not on a large scale, nor under conditions suitable to serve as a basis for statistical treatment.

In discussing this subject, consideration of the peculiar condition under which production is carried on, and of the noncommercial uses of the product, is of importance. No comparison of the returns in 1902 with those of the Eleventh Census is practicable, owing to the different methods by which these reports were made up. Moreover, it is difficult to present any careful analysis of the figures, and the results necessarily are uncertain. The data in Table 1 are based upon trustworthy information derived from the operators.

The value of the turquoise produced amounted to $130,000, or 39.6 per cent of the whole, and of sapphire, $115,000, or 35 per cent. Much of the production of precious stones was more or less accidental, picked up by prospectors for other minerals, or by excursionists along the beaches. This fact will explain the apparent inconsistency between the small number of mines and the large number of operators reported. It will be readily understood that in such cases no items of expense are properly chargeable. The statistics following, with the exception noted above, are for those companies actively engaged in the systematic exploitation of precious stone deposits. The peculiar condition existing, however, should not be lost sight of.

There were 3 mines, 1 each in California, New Mexico, and North Carolina, reported idle during 1902.

Table 1.—*Summary: 1902.*

Number of mines or quarries	46
Number of operators	460
Salaried officials, clerks, etc.:	
Number	22
Salaries	$28,687
Wage-earners:	
Average number	108
Wages	$88,017
Miscellaneous expenses	$7,481
Cost of supplies and materials	$17,781
Value of product	$328,450

Capital stock of incorporated companies.—Of the 460 operators reported, 449 are classified as individuals, 1 as a firm, and 10 as incorporated companies. Three of the individuals only, however, are miners of precious stones in the strict sense of the word. Of the 10 incorporated companies 1 is located in Arizona, 3 in California, 2 in Montana, 3 in New Mexico, and 1 in North Carolina. The following table shows the details of their capitalization:

Table 2.—CAPITALIZATION OF INCORPORATED COMPANIES: 1902.

	United States.	Arizona.	California.	Montana.	New Mexico.	North Carolina.
Number of incorporated companies	10	1	3	2	3	1
Capital stock issued (all common)	$1,562,078	$85,000	$600,078	$400,000	$452,000	$25,000
Total authorized:						
Number of shares	1,461,400	100,000	598,500	400,000	450,400	2,500
Par value	$2,129,000	$100,000	$1,152,000	$400,000	$452,000	$25,000
Total issued:						
Number of shares	1,042,978	85,000	105,078	400,000	450,400	2,500
Par value	$1,562,078	$85,000	$600,078	$400,000	$452,000	$25,000
Dividends paid	$20,000			$20,000		

No bonds or preferred stock appear to have been issued by these companies. Of the 1,461,400 shares of common stock authorized, there were 1,042,978 shares issued.

Employees and wages.—Of the $116,704 reported as paid for salaries and wages, $28,687, or 24.6 per cent, was paid to salaried employees, and $88,017, or 75.4 per cent, to wage-earners. In Table 4 is given the average number of wage-earners employed each month during the year. One hundred and forty-one men were given employment during June, while in March only 87 were reported. The average number for the year was 108. Table 4 shows also the average number of wage-earners at specified daily rates of pay. There were 79 wage-earners, or 73.1 per cent of the whole number, classed as miners. Of these, 61, or 77.2 per cent, received $2 or more per day, and only 18, or 22.8 per cent, less than that amount. Of the total number of employees, 82, or 75.9 per cent, received $2 or more per day, and 26, or 24.1 per cent, less than $2. Four machinists, or other mechanics, were employed, as were also 5 miners' helpers, and 20 employees doing miscellaneous work. All the miners' helpers earned from $3 to $3.24 per day.

Supplies, materials, and miscellaneous expenses.—Next to wages, the principal item of expense was for supplies and materials, for which $17,781 was expended. Of the $7,481 reported as miscellaneous expenses, $437 was for rents and royalties of mining plants, and $7,044 for office rent, taxes, insurance, and other sundries.

The yearly production of precious stones by kinds and value, as reported by the United States Geological Survey, is given in Table 3.

TABLE 3.—PRODUCTION OF PRECIOUS STONES IN THE UNITED STATES: 1896 TO 1902.

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

STONE.	1896	1897	1898	1899	1900	1901	1902
Total	$97,850	$130,675	$160,920	$185,770	$233,170	$289,050	$328,450
Diamond	None.	None.	None.	300	150	100	None.

A detailed summary of the statistics for the mining of precious stones in the United States during 1902, where the operations were followed on a commercial basis and warranted statistical treatment, is given in Table 4.

DESCRIPTIVE.

Precious stones derive their value chiefly from their rarity. Other qualities that influence their value are beauty of color, hardness, and the caprice of fashion. Under this classification a distinction could be made between precious and semiprecious stones, but it is not observed in this discussion. Precious stones include the diamond, the sapphire, the ruby, and the emerald; semiprecious stones include a wide variety of other gem minerals. The opal and the pearl are sometimes classed as precious stones, although the latter is not strictly a mineral product. In ordinary speech the precious or semiprecious stone signifies a gem cut or polished for ornamental purposes. In mineralogy the term is used to designate a class of minerals of sufficient hardness to scratch quartz, which are without metallic luster,

although generally brilliant and beautiful. In archaeology the term is restricted to engraved stones, such as intaglios and cameos. A jewel is a gem that has been mounted.

In the report of the Eleventh Census upon "Mineral Industries," page 669ff, an account is given of the occurrence and production of precious stones in this country during the year 1889. The present discussion treats only of the discovery and production of precious stones in the United States since that time.

Diamond.—The diamond, the hardest of known substances, is pure carbon, which crystallizes in the isometric system, generally in an octahedral form. Its specific gravity is 3.525. It occurs in a great variety of colors, ranging through all the shades of the spectrum, occurring most frequently as white, yellow, or brown, and rarely as red, rose-red, blue, or green. By far the greatest number of diamonds come from South Africa, but they are found also in Brazil, India, Borneo, and occasionally in North America.

In the United States diamonds have been found at various points, but they have been few in number, and mostly of small size. Their occasional occurrence in California and east of the southern Alleghanies has been known for fifty years. Since 1890 a few others have been found in these regions, and some in the Northwestern states, varying from one-third of a carat to 21 carats in weight.

The northwestern diamonds are very interesting as being contained in the deposits of the glacial drift, scattered along an irregular line of some 600 miles, from Wisconsin to the vicinity of Cincinnati, Ohio. All the material distributed by this ancient glacial action has been brought down from the north, and therefore the source of these diamonds is somewhere in the unexplored regions of Canada and not in the United States. Geologists recognize two distinct drift deposits in the Western states, called the older or Illinoian drift, and the later or Wisconsin drift. Some of the diamonds found in Indiana and in Wisconsin are referred to one of these drifts and some to the other, though most of them belong to the later. The whole number of diamonds actually known from these glacial deposits amounts to about 25, over half of which are from Wisconsin and one-third from Indiana.

The localities of discovery during the period since 1890 are as follows:

Alabama.—Shelby county, one of 4½ carats. Lee county, one of 3 carats.

California.—A number of localities, chiefly in the central portion of the state, in connection with the hydraulic gold washings of Amador, Butte, Eldorado, and Nevada counties. A single diamond is reported from Tulare county, and a number of very small ones in the gold sands of streams in Del Norte and Trinity counties. No large stones have been found in California, and nowhere are they abundant enough to lead to any mining for them. Nevertheless some handsome ones have been casually obtained in the central counties above named, chiefly in the ancient gold-bearing gravels overlaid by lava flows, and fragments of diamonds crushed by the stamp mills are not uncommon in the flumes and sluices. Most of the stones found within recent years have come from the vicinity of Placerville, Eldorado county.

Indiana.—Brown county, five—one of 2 carats, others very small. Morgan county, three—one of 3¾ carats, others very small.

Kentucky.—Cabin Fork creek, Russell county, one.

Michigan.—Dowagiac, Cass county, one of 10⅞ carats.

Ohio.—Milford, Clermont county, one of 6 carats.

Tennessee.—Koko creek, Tellico river, Monroe county, several reported. Union Crossroads, Roane county, one of 3 carats. Luttrell, Union county, one of $1\frac{13}{16}$ carats.

Wisconsin.—Plum creek, Rock Elm township, Pierce county, several very small stones. Oregon, Dane county, one of $3\frac{13}{16}$ carats. Kohlsville, Washington county, one of 21 carats. Saukville, Ozaukee county, one of 6⅜ carats. Eagle, Waukesha county, one of $15\frac{13}{32}$ carats. Burlington, Racine county, one of $2\frac{1}{16}$ carats.

The whole subject of the Indiana occurrence is fully described by the state geologist, Prof. W. S. Blatchley,[1] in his annual report for 1902. The geological features of the region are first treated with special reference to the distribution of the drift deposits in central Indiana. These have been known since 1850 to contain gold, and a large amount of local prospecting and panning has been carried on along the streams for years. The gold is found associated with magnetic iron sand, menaccanite, and other heavy minerals. It is in these auriferous sands that diamonds have been found at intervals for some twenty-five years, but especially of late. Some of the diamonds belong certainly in the second, or later, drift, like most of those in Wisconsin; others found south of that line but within the margin of the older drift belong, perhaps, to the older deposits instead of having been washed out from the later beds and carried south by streams, as formerly supposed. The terms "earlier" and "later" are now frequently replaced by "Illinoian" and "Wisconsin," and designate the two glacial drifts, but these terms may be misconceived as to their geographical signification and hence require explanation. The center of ice movement in the glacial era was determined some years ago by Canadian geologists as having traveled or shifted toward the east from the west. Of the two ice invasions that spread over the northern United States, the earlier is called by some geologists the "Illinoian," as having covered a large part of that state not reached by the later one; while the name "Wisconsin" is applied to the later by Prof. T. C. Chamberlin, because it extended westward to a portion of that state not covered by the earlier, and formed there what he terms the Wisconsin boundary, although its source was far east of the earlier drift, and it forms the main deposit of the Eastern states.

Professor Blatchley's list comprises eight diamonds that he himself has seen, and seven more of which he has credible information. The earliest published mention of the occurrence of diamonds in Indiana was made by the late Prof. E. T. Cox, state geologist, in his annual report for 1878, page 116, although the well-known artist, Mr. Daniel Beard, of New York, owns a

[1] Gold and Diamonds in Indiana, by W. S. Blatchley. Twenty-seventh Annual Report of the Department of Geology and Natural Resources of Indiana, Indianapolis, 1902.

fine diamond of about 2 carats found in Indiana before that year.[1] Professor Cox mentions several diamonds, of which this may be one, as found in the drift of Brown and Morgan counties, and refers to them with interest because of their evident transportation from a far northern source. Of the eight stones seen by Professor Blatchley, four are from the newer and four from the older drift, or at least from the area covered by it south of the margin of the newer. The list in detail is as follows:

1. The Stanley diamond, found in 1900, by Calvin Stanley, while panning for gold in Morgan county, on a branch of Gold creek, 3 miles northwest of Centerton, and 3 miles west of Brooklyn. It was found in the bed of the stream at the base of a cliff of shale. The stone was an octahedron weighing $4\frac{7}{8}$ carats, with a yellow tinge and a small black spot. It was purchased first by Mr. R. L. Royse, of Martinsville, Ind., and by him sold to C. E. Nordyke, of Indianapolis, who had it cut into two stones in Cincinnati. These have a peculiar greenish yellow tint, and weigh respectively $1\frac{1}{8}$ and $1\frac{1}{16}$ carats.

2. The Young diamond, found by a local gold hunter, Mr. W. W. Young, in 1898, on Lick creek in Brown county, $4\frac{1}{2}$ miles south of Morgantown. It is an oblong dodecahedron of $1\frac{9}{32}$ carats, white with a yellow cast, and very clear and flawless. It is retained by the finder.

3. An elongated hexoctahedron, of pink color, but only one-eighth of a carat in weight. It was found, like the last, on Lick creek, by Mr. John Merriman, and now belongs to Mr. Nordyke, of Indianapolis.

4. A yellow hexoctahedron of three-sixteenths of a carat, found by Mr. Merriman on Lick creek. It is now owned by Mr. Royse.

5. A light brownish yellow hexoctahedron of five thirty-seconds of a carat, found and owned by Mr. Royse.

6. A bluish rhombic dodecahedron, weighing eleven-sixteenths of a carat, found by Mr. Merriman on Gold creek, Morgan county, now also belonging to Mr. Royse.

7 and 8. These are pinkish crystals, neither of which exceeds one-eighth of a carat, found in May, 1903, by Mr. Royse. They were taken from the tailings of sluice boxes on the farm of Doctor Cook, near Brey, in Morgan county.

The first, and the last three, from Morgan county, are from the newer or Wisconsin drift, the others, from Brown county, are from the older or Illinoian area.

Sapphires and rubies.—The sapphire, ruby, oriental topaz, oriental amethyst, and oriental emerald are names given respectively to the transparent blue, red, yellow, purple, and green varieties of corundum, which is nearly pure alumina, Al_2O_3. The colors of these minerals are ascribed to the presence of minute quantities of metallic oxides. Their specific gravity ranges from 3.97 to 4.05, and their hardness is 9. Rubies are found in Burma, Ceylon, and Siam. Sapphire also occurs in those countries, as well as at the Simla pass in the Himalayas, and in Australia.

The great hardness of corundum gives it a special value for polishing purposes, and the amount produced for such uses during 1902 has been treated under "Abrasive materials." Although corundum is found in the crystalline rocks along the Appalachian mountains from Massachusetts to northern Georgia, few gems of any special value have been found, except in the Cowee valley in North Carolina, where true rubies are obtained to some extent, although mining has ceased for a few years past.

Other deposits in which these gems are found exist in Montana. Sapphires of the finest quality are now mined in Yogo gulch, and others of much beauty are found at other points in the same state.

Until within a few years, these gems had been found only occasionally in the United States—nearly all of them in North Carolina—and were principally cut from small transparent portions of the colored corundums that were otherwise more or less opaque. Corundum is mined in that state extensively as an abrasive material, and ruby and sapphire are simply transparent varieties of it. The Montana gems began to attract notice about 1869, and for some years they were collected abundantly from the bars of the upper Missouri east of Helena; these were of varied and often beautiful tints of pink, blue, green, and intervening shades, but rarely of the deep colors in favor for jewelry. The latter, the rich blue sapphires equal to those of India, have since been found at Yogo gulch, in Fergus county, and active work in mining them from the rock has been carried on for several years by the New Mine Sapphire Syndicate and the Burke and Sweeney Company. Two other important localities in Montana are at Rock creek, in Granite county, and Dry Cottonwood creek, in Deerlodge county, worked by the American Gem Syndicate Company. The former of these yields a wonderful variety of colors, often very beautiful, but few that have the deep shades most valued in the gem market. No locality in the world has shown such variety of tints in sapphires—pink, reddish brown, brown, yellow, green, etc., with occasionally a ruby of the paler type of Ceylon. Gems of considerable value have been annually mined at Yogo gulch for several years past. Fine sapphires of the "cornflower" and "velvet" blue of the best oriental stones have been obtained, weighing as much as 3 carats, and a few as high as 5 and even 7 carats, after cutting. Besides those used for setting, large quantities of small ones from both these localities have found ready sale for watch jewels and bearings; indeed, more have been sold for this purpose than for gems.

[1] This diamond, from facts that Mr. Beard has given the writer, must have been found as early as 1826.

True rubies have been found, and to some extent mined, in the Cowee valley, Macon county, N. C. Some of them have the rich and peculiar "pigeon's-blood" color of the finest rubies from Burma, but the crystals are small or imperfect, and the yield thus far has been quite limited. The operations were conducted by the American Prospecting and Mining Company.

Emerald.—True emeralds, suitable for cutting and setting, can hardly be said to be found in the United States. It is true that large and very fine crystals of emerald were obtained at Stonypoint, Alexander county, N. C., in 1877; but these, although valuable and beautiful as specimens, were not clear enough to cut into gems. More recently a locality has been opened at Crabtree, Haywood county, in the same state, where small and handsome emerald crystals, both translucent and opaque, occur thickly in the white feldspar and quartz of a vein of pegmatite (coarse feldspathic granite). This green and white mixture is very pleasing, and as the three minerals have nearly the same degree of hardness, the whole can be cut and polished together, making a novel and beautiful ornamental stone. Pieces are cut *en cabochon*, i. e., rounded, not faceted, showing sections of the emerald crystals in different directions in the white mass. This material has been introduced into ornamental and minor jewel work under the name of "emerald matrix," by the American Gem Company.

Beryl.—Beryl is essentially the same mineral as emerald, though of paler shades and much less esteemed. Fine transparent beryls, however, are choice gem stones, and several varieties of them are found in the United States. Among these are emerald beryls, of rich light-green shades; aquamarines, faintly tinged with green; golden beryls, of a rich yellow; blue beryls, sometimes almost as beautiful as pale sapphires; and rose beryls, of light-pink color. Some very fine gems have been cut from crystals of these kinds, especially from Topsham, Me., in the quarries of the Trenton Flint and Spar Company. Other fine gems come from Connecticut, North Carolina, and Colorado. In North Carolina, near Sprucepine post office, many fine beryls—some of the richest blue color ever found—have been mined by the American Gem Company. The finest and largest aquamarine known is from Stoneham, Me. Golden beryls of much beauty have been cut from material mined at Merryall, in Litchfield county, Conn. Green and blue beryls have been found in North Carolina, and aquamarines at Mt. Antero, Colo. The discoveries of fine gem material are, however, not frequent nor in large amount, so that there is no systematic mining or regular production.

Topaz.—Topaz is a fluosilicate of alumina and crystallizes in rhombic prisms with a hardness of 8. The true topaz occurs but sparingly in the United States, although here and there it has been found fine enough to yield choice cut gems. Still, as with many other gem minerals, there is no locality that furnishes any steady supply. Within recent years a few white topazes have been obtained at the Stoneham, Me., and Chatham, N. H., localities; also at Cheyenne mountain, Pikes Peak, and at Nathrop, Colo. They are generally sherry-colored at the former localities, in crystals weighing up to 3 ounces each; at Nathrop in smaller brilliant crystals.

Very recently a number of topaz crystals have been obtained near Ramona, San Diego county, Cal. The crystals vary from quite small ones of great brilliancy up to 1 or 2 inches long and half that diameter. Most of them are perfectly colorless, but some have the pale blue or greenish blue of the topazes from Sarapulka, in the Urals. The larger crystals are somewhat dull externally, but almost all are clear within and would cut into handsome gems.

Garnet.—The name garnet is used for a well-defined group of minerals very closely related in both chemical and physical properties. They are complex silicates of alumina, with varying amounts of lime, magnesia, iron, manganese, and other metallic oxides, which, by their presence in different proportions and combinations, impart various colors to the compound. All the garnets crystallize in the isometric system. Several of the varieties are richly colored, and when transparent are favorite gem stones, though not of the highest value.

The kinds chiefly used in jewelry are those known as precious garnet, or almandine, Bohemian garnet, or pyrope, and manganese garnet, or spessartite. The two former present deep crimson shades, and the latter is of an orange-red or light red-brown color. These are all found in the United States, but there is no regular production, save to some extent of pyrope, in Arizona and New Mexico, and of a beautiful light purple-red garnet known as rhodonite, an intermediate variety between pyrope and almandine, in Macon county, N. C. This latter is among the discoveries of the last decade, having attracted attention and been more or less mined since 1897, and the stones produced have been cut and sold as rather novel American gems. The locality is in the Cowee valley, where the ruby corundums before alluded to have been found. The garnets occur chiefly in the valley of Masons branch, a small stream flowing from Lisle Knob, a spur of the Cowee mountains. All are found in rather small pieces, but their color is a beautiful light red, and their luster when cut is remarkably brilliant. They were at first taken for almandine, and so reported, but analysis shows that their composition lies between that variety and pyrope, and hence they were given the separate name of rhodonite (from the Greek *rhodon*, a rose). In the years 1900 and 1901 the output of these garnets amounted to $20,000 and $21,000, respectively. It has since fallen off somewhat, but work is actively carried on, and large pieces have been obtained, up to 43 and even 59 carats.

Pyrope garnets of fine quality are found in several

localities in New Mexico and Arizona, and are frequently miscalled Arizona rubies. The principal locality in New Mexico is on the Navajo Indian reservation, and the finest large specimen from there is the property of Mr. W. T. Kaufman, of Marquette, Mich. It is more than half an inch in diameter, weighs 11⅛ carats, and has a magnificent red color, equal to any garnet that the writer has seen from any locality. They are also found at some places in northern Arizona, and one of the finest, from near Fort Defiance, was figured by the writer several years ago.[1] They occur loose in the soil, on or near the surface, and are gathered by Indians, soldiers, and cowboys, principally from around ant hills and scorpion holes, where they are brought up and thrown out by the insects. Their source is doubtless in peridotite rocks, from which they are weathered out in the decomposition of the outcrops. In the years since 1896 the annual sales have been estimated at from $1,000 to $2,000.

Spessartite (manganese garnet) was found in magnificent specimens twenty years ago in the albite mine at Amelia Court House, Va., and splendid gems were cut from these. But unfortunately the mine has been closed and abandoned for years past, and one of the finest localities for American gems has thus ceased yielding. Very recently beautiful crystals have been found at Ramona, in San Diego county, Cal. Some are 15 millimeters in diameter or more, of a rich orange-brown color, and the smaller crystals exceedingly clear and brilliant. This may prove to be a source of choice gem material, although as yet the amount of it present has not been ascertained.

Many other varieties of garnet are known to exist in various parts of the country, and some gems have been cut from them at times, but there is no regular production. Several kinds are reported in Tulare county, Cal., and one of great rarity and beauty at Carrville, Trinity county, in the same state. This is the emerald-green chrome garnet, known as uvarovite, which furnishes beautiful gems when in crystals of any size. This was reported in 1900 as found in small crystals, lining cavities in chrome iron, very richly colored and brilliant, but none of the crystals was more than 3 millimeters in diameter, and no further exploration seems to have been made since.

Tourmaline.—Tourmaline belongs to the rhombohedral system of crystallization, occurring in prisms, the sides of which are generally striated and channeled. The transparent variety is of a hardness of 7.5, its specific gravity ranges from 3 to 3.25, and in composition it is a very complex silicate of alumina. Many different colors are found, ranging all the way from a colorless variety through red, green, blue, and brown, to black. These differences in color are chiefly due to the varying amounts of manganese and iron present. The gem is dichroitic; thus when viewed through the side it may be a transparent green, but either opaque or yellow-green when viewed endwise of the prism.

Tourmaline was but little known in jewelry ten years ago, although some very beautiful gems had been cut from the transparent red, green, and blue crystals obtained at Paris Hill, Me., and Haddam Neck, Conn. Some mining had been done at these places, and many splendid specimens obtained. But within a few years past, wonderful discoveries of gem tourmaline have been made in southern California, at Pala and Mesa Grande, in San Diego county, and in the San Jacinto mountains in Riverside county. The crystals found at these localities are of great size and beauty, and gems have been cut from them in abundance. A single collection of these crystals has been valued at $10,000. The prevailing colors are pink, salmon, and red, all in very rich shades, also fine green and blue, though less frequently in these colors than those found at Mt. Mica and other localities near Paris, Me. Tourmaline is peculiar in that it often presents two or three different and even contrasting colors in the same crystal, which sometimes shade into each other, but often present a sharp line of contact. Advantage has been taken of this feature, which is marked in the California crystals, to produce in jewelry the novelty of parti-colored gems. Beautiful cut stones may now be seen that are half red and half green, or showing other similar contrasts. Many of the larger stones are somewhat flawed; these are often cut *en cabochon* (rounded), and many also as oriental beads. Some present a fibrous texture, and on cutting yield a cat's-eye effect. Many of the larger and less pure pieces have been cut into regular forms for ecclesiastical and other art work. Remarkable crystals possessing the cat's-eye properties have been found at the mine of the Himalaya Mining Company, at Mesa Grande, California.

There are two mines at Pala, Cal., owned by the Pala Lithia Company, one of which yields beautiful specimens of rather small and opaque pink tourmaline crystals, in radiated groups, in lilac lepidolite (lithia mica), none of which, however, is suitable for gem material. The mine is worked for the lepidolite, as a source of lithia compounds, and specimens find a ready sale to collectors and museums. The other mine, which has only recently been discovered, carries large and splendid crystals of tourmaline of mingled colors, and also a new gem named Kunzite, a transparent lilac spodumene.

[1] Gems and Precious Stones of North America, 1892, Plate III, fig. A.

The localities of Mesa Grande and San Jacinto, which have been furnishing beautiful tourmaline adapted for use as gems, have been steadily worked for several years. Meanwhile, tourmaline is coming to be generally known and esteemed in jewelry as it never has been before.

The entire output of tourmaline in the country is estimated in the reports of the United States Geological Survey as amounting to $15,000 in 1901 and to $30,000 in 1902.

Kunzite (lilac spodumene).—Reference has been made above, under tourmaline, to the discovery of this new and interesting gem stone at Pala, Cal. This locality is remarkable for its lithia compounds, among which are the colored tourmalines and the spodumene, both of which contain lithia in small amounts, combined with silica, alumina, and other oxides.

The mineral spodumene is usually obtained in large, opaque, whitish crystals, but from time to time small specimens, often richly colored and transparent, are found. The three characteristic varieties of the latter are a clear yellow gem spodumene from Brazil,[1] the green "hiddenite" or "lithia emerald" of North Carolina,[2] and small lilac specimens sometimes found in Connecticut.[3] These last are without doubt remnants of large crystals, which must have been very beautiful. Spodumene is particularly subject to alteration, and when found has usually lost all its transparency and beauty of tint.

Large and magnificent crystals of unaltered spodumene, of rich lilac color, have now been discovered near Pala, San Diego county, Cal., in connection with other lithia minerals.[4] This locality has yielded crystals measuring 10 by 20 by 4 centimeters, perfectly clear, of a rose-lilac tint, varying with the spodumene dichroism from a very pale color when looked at across the prism to a rich amethystine hue observed longitudinally. No such spodumene has ever been seen before, and the discovery is of great mineralogical interest. The crystals have been etched by weathering like the hiddenite variety. When cut and mounted parallel to the base, they furnish gems of great beauty, entirely new in jewelry, and make a notable addition to American gem stones.

An extended investigation into certain optical properties of the gem minerals in the Tiffany-Morgan and Bement collections in the American Museum of Natural History, New York, was conducted jointly by the writer and Prof. Charles Baskerville, of the University of North Carolina, during the autumn of 1903. These experiments developed marked and interesting peculiarities of the new mineral.[5] Doctor Baskerville says of it in the American Journal of Science, July, 1904:

> I have submitted large crystals to the action of ultraviolet light with very positive continued phosphorescence. When submitted to bombardment of the Roentgen rays of high penetration for several minutes, a fluorescence is observed, and on removal to a dark chamber it exhibits a persistent, white luminosity not observed with this class of minerals, as learned by experiments with altered and unaltered spodumene from the localities mentioned, including cut stones and such handsome crystals of hiddenite as afforded by the collections mentioned. I have been able to excite a crystal (2 by 4 by 10 centimeters) by the action of the X rays for five minutes sufficiently to cause it to photograph itself when subsequently placed directly upon a sensitive plate (thin white paper being interposed) and allowed to remain in an especially constructed padded black box in a dark room for a period of ten minutes. The material is penetrated by the rays, as shown by a cathodegraph. The excitation is not superficial, but persists throughout the mass.

Doctor Baskerville submitted crystals to the action of emanations of radium bromide, 300,000 activity, especially imported from the Société Centrale des Produits Chimiques at Paris. After a few minutes' exposure the mineral began to glow, and its phosphorescence was most pronounced after the removal of the radio-active body. A five-minute exposure to 125 milligrams of radium bromide caused 600 grams of the gem material to become luminescent in the dark after removal of the radium preparations. This remarkable property was not exhibited by hiddenite or any other specimens of spodumene examined. Doctor Baskerville proposed for it the name of "Kunzite."

Californite.—Californite (vesuvianite)[6] a mineral which promises to be a notable addition to the increasing list of semiprecious or ornamental stones found in the United States, has recently been discovered in California. This is not a new mineral species, properly, but a compact massive variety of vesuvianite (idocrase). It was first announced in the report of the United States Geological Survey for 1901,[7] by the writer, as having been found by Dr. A. E. Heighway, on the South Fork of Indian creek, 12 miles from Happy Camp and 90 miles

from Yreka, in Siskiyou county, Cal. Here a hard and handsome stone, varying in color from olive to almost grass-green, and taking a fine polish, outcrops for some 200 feet along a hillside about 100 feet above the creek, and large masses have fallen into the bed of the creek. At first it was supposed to be jade (nephrite), but upon analysis proved to be vesuvianite. The fallen pieces were in some cases as much as 5 feet square and 2 feet thick, of excellent quality for polishing, and of varying shades of light to dark green. The associated rock is precious serpentine.

A very similar mineral was discovered some years ago at one or two places in the Alps, and, like this, was at first described as jade, but on analysis proved to be massive vesuvianite. The likeness to green jade is very marked in both these and the California mineral, and the mistake is not surprising.

The following analysis was made through Prof. F. W. Clarke, chief chemist of the United States Geological Survey, by Mr. George Steiger, in the spring of 1903:

Analysis of vesuvianite from Siskiyou county, California.

SiO_2	35.85	TiO_2	0.10
Al_2O_3	18.35	P_2O_5	0.02
CaO	33.51	H_2O- (below 100° C.)	0.29
Fe_2O_3	1.67	H_2O+ (above 100° C.)	4.18
FeO	0.39		
MgO	5.43	Total	99.84
MnO	0.05		

The analysis is essentially that of a normal vesuvianite, though the percentage of water is unusually high. The lime and the iron are below the average, and the titanium and phosphorus are exceptional occurrences.

The mineral is compact, extremely tough, and readily takes a high polish, quite as beautiful as that of nephrite (jade), with which it was at first confounded. The hardness is 6.5 and the specific gravity (from two determinations) is 3.286. The luster is vitreous, often inclining to resinous, and the streak is white. The color is a yellow leek-green, with inclusions of a darker green, which are generally more translucent than the surrounding mass.

This interesting mineral exists in large quantity, and could be cut into a variety of ornaments, in the same way as jade, nephrite, and chrysoprase. It is a form of vesuvianite distinctive enough to receive a special variety name, which, if appropriate and euphonious, would undoubtedly aid the sale of the stone in the arts. The name of "Californite" has been proposed for it.

The discovery of what appears to be the same mineral has recently been announced from two other localities in California quite remote from the first. One of these was reported by that indefatigable prospector, Mr. M. Braverman, of Visalia, as existing in Burrough, in Fresno county, a mile and a half from Hawkins schoolhouse and 32 miles east of Fresno city. The material is pale olive green, translucent, with darker spots in a paler mass. It breaks with an uneven fracture, slightly splintery and partly crystalline, and hence much resembles the material from Siskiyou county. The other locality is apparently not very far from the last mentioned. It is said to be in Tulare county, near the town of Selma, which, though in Fresno county, is near the Tulare line. Here the mineral is of richer color, at times resembling the tint of apple-green chrysoprase, for which it was at first mistaken.

An analysis was made of the green mineral (No. 1) below, through the courtesy of Prof. F. W. Clarke, chief chemist United States Geological Survey, by Mr. George Steiger. In comparison is shown also the analysis of a remarkable associated mineral (No. 2), which proved to be a peculiar variety of garnet.

Analysis of two minerals from California.

	No. 1, Californite, green.	No. 2, Garnet, white.

Chlorastrolite and mesolite.—In the region about Lake Superior occur two or three peculiar little minerals that have attained some value as "local" gem stones. These, in the order of their importance, are chlorastrolite, thomsonite (properly mesolite), and lintonite; besides one or two other varieties, rarer and of less account. These are all nearly related in composition, being silicates of alumina with varying amounts of lime and oxide of iron. They are all found as rounded nodules, not from wear, however, but natural, as being the filling of small ovate cavities (originally bubble holes) in the trap rocks of the region. As the rocks decompose these harder nodules fall out, and are rolled on the lake beaches or by streams, and are often supposed to be pebbles, but they are not such in reality. They seldom exceed half an inch in diameter, but when polished they make quite pretty stones, and are in considerable demand for local jewelry, as rings, studs, and the like.

Chlorastrolite is found only at Isle Royale, Lake Superior, where it abounds in the trap and on the beaches. It has a characteristic color, from bluish to

olive green, and a peculiar radiated mosaic-like structure or pattern. Prof. N. H. Winchell, of the University of Minnesota, has studied these minerals carefully, and shown that the chlorastrolite passes into a substance identical with the so-called thomsonite, the two forming the extremities of a series of closely-related minerals that fill such cavities in igneous rocks of this character. As the proportion of iron diminishes the chlorastrolite loses its color and its pretty little stellate structure, becomes pale and even whitish, and graduates into a white or pinkish body like the mesolite. The best mesolite comes from Grand Marais, Minn., and is in similar nodules, ranging from white to reddish and brown, in concentric zones or bands. This mineral Professor Winchell shows to be not thomsonite, as supposed, but the related species, mesolite, and this latter name should be substituted in these cases for the other, which is erroneously applied. Lintonite is a green mineral with something of the radiated pattern of chlorastrolite, but belongs really to thomsonite proper.

The demand for these little semigems is pretty steady, and the value of the output is considerable. They are not mined, but simply gathered along the beaches, etc., and the production for several years past is estimated to amount to $1,000 annually for thomsonite (i. e., mesolite) and from $3,000 to $5,000 for chlorastrolite.[1]

Opal.—Prior to 1889 no precious opal had been found in the United States. At about that time, however, and during the subsequent decade, several occurrences of it were discovered, and mining operations were undertaken at some points with apparent promise of successful yield. But for various reasons no important or continuous production has been developed as yet, although the igneous rocks of Washington, Idaho, Oregon, California, Nevada, and Utah, undoubtedly contain much handsome opal.

The first important opening was in 1890, near Moscow, Latah county, Idaho, close to the Washington line. Buildings were erected and a post office called Gem City was established. Fine opal was present in the trachyte rock, and for a year or two there was considerable production. In 1891 the value of the output was estimated at $5,000. For some time past, however, little has been heard of this formerly promising locality.

Other occurrences were noted at about the same time. One of these was in Morrow county, Oreg., where several thousand dollars' worth of specimens were said to have been obtained in 1892, and many were exhibited at the Spokane fair. Another was at Opaline, in Owyhee county, Idaho, and exhibits of these were made in the Idaho section of the Mining Building at the Columbian Exposition of 1893. Another occurrence was reported in 1895, near Salmon city, Lemhi county, Idaho, where beautiful opal was found in bowlders of trachyte, and finally traced to the ledge whence it had come. Many very handsome pieces were obtained, and the mineral was present in great variety of color and quality, but no definite work seems to have been undertaken.

In the same year Mr. Don Maguire, of Ogden, Utah, described an occurrence in Lemhi county, Idaho, on Panther creek. This has been recently opened, and will be referred to again.

In 1894 banded opal in large sheets, with hyalite, was reported from Beaver valley, Utah, near Granite Peak, apparently in connection with an ancient geyser, but no work seems to have been attempted there.

In 1897 other localities of precious opal were described at Durkee, Oreg., and at Dunsmuir, Siskiyou county, Cal. Work was undertaken at the former place, but practically nothing has been heard of it since.

Recently, in 1902, one or more promising occurrences have been announced in southern California, in the region of the Mojave desert. One of these is in San Bernardino county, about 25 miles north of Barstow, the junction of the Santa Fe and California Southern railroads. Here opal occurs in veins and pockets in a porphyritic dike about 2 miles in length. Much of it is semiopal, of various colors, some a beautiful amber-yellow, and with these occur precious and fire opal. The locality is promising, but needs to be explored and developed. In Tulare county, also, are found some beautiful semiopals that might be valuable in ornamental art work. One of these, from near Yokohl, is transparent yellow and amber-like; another is from the chrysoprase mine near Visalia. It is translucent green, and has been called chrysoprase opal, or chrysopal, by the discoverer, Mr. M. Braverman. The Idaho locality at Panther creek, Lemhi county, before alluded to, has been rediscovered and described during 1902. Opal of many varieties and colors is abundant here, in a porphyritic dike, traced for a mile and a half, parallel to the creek, and at times as much as 150 feet wide. Much of it is very beautiful, but it is also very brittle, and goes to pieces in extracting it, so that stones of any size are difficult to procure. This locality, however, when more fully examined, may yet prove to be valuable.

There are many minor occurrences that have been noted and many varieties of semiopal that may hereafter yield material of some value in the arts. Gem opals, however, are not yet produced to any extent or with any regularity in the United States, although there is considerable promise at several points.

Turquoise.—Turquoise is a hydrated phosphate of alumina, containing small quantities of copper, iron, or manganese. The mineral varies in color from a fine sky blue to many shades of bluish green, and to apple green and dark green, which show no blue whatever. The hardness of the mineral is 6, and its specific gravity is 2.75.

[1] United States Geological Survey, "Mineral Resources of the United States," 1898 to 1902; table of production of precious stones.

Turquoise was almost unknown in the United States when the census of 1890 was taken. A few specimens in collections of minerals attested its existence at some points in Arizona and Nevada, and objects worked by the Indians of the Southwest were known to be abundant, but there was no production of it, and all the turquoise used in jewelry came, as it had for centuries past, from the mines in Khorassan, in eastern Persia. Since then a remarkable change has taken place, and the Southwestern states and territories are now furnishing the main supply for the world. Turquoise has been discovered at a number of points in large quantities and of fine quality. It is known to exist in Arizona, New Mexico, Nevada, and southern California, while some localities are reported in Texas and southern Colorado. The main production is in New Mexico, in Santa Fe and Grant counties, and at Turquoise mountain in Arizona. The California localities operated by the Himalaya and the Toltec companies are northeast of Manvel, in San Bernardino county. At almost every point where the mineral is found there are interesting and conspicuous evidences of ancient workings in pre-Columbian times; in many cases these were plainly both extensive and long continued; stone tools and similar objects are abundant, and at some points remarkable rock carvings are to be seen, especially about the California localities. The Toltec Turquoise Company has also operated other mines near Manvel, Cal., over the line in Lincoln county, Nevada.

Turquoise is now being regularly mined in New Mexico, at perhaps a dozen places, by the Azure Turquoise Company, the American Turquoise Company, the Gem Turquoise Company, and by Mr. A. C. Young; and in Arizona by six companies, among them the Aztec Turquoise Company. In 1902 turquoise was discovered in Alabama, on property of the Otero Company, near Idaho, Clay county, about 95 miles east of Birmingham, in the region of the Talladega mountains. This mineral sometimes loses or changes its color, and for this reason several of the above-named companies engrave a trade-mark upon the back of every stone that they sell as a guarantee that the company will replace it with another stone in case of any failure of quality appearing within six months after its sale to the retail purchaser. Thus, all stones from the American Turquoise Company are marked with an "A," from the Azure Company with a circle, from the Toltec Company with a "T," etc. This assurance to the buyer is a marked improvement on the methods of the Persian dealers, who were wont to decamp for parts unknown during the night after a sale. Some of the companies claim, indeed, that their stones never change color, but they furnish a guarantee, notwithstanding.

In 1900, according to official reports, the output from the oldest and largest mine, at Los Cerrillos, N. Mex. (now called Turquesa), had amounted to a total of over $2,000,000 since 1890. The production from all the American mines was estimated at $118,000 in 1901, and at $166,500 in 1902. A single stone has been sold for as much as $3,000.

Utahite and prosopite.—Several handsome and interesting minerals, related to or resembling turquoise, have been identified in Utah during the last decade. Some of these have been largely sold as specimens, though as yet they have not been found in sufficient quantity to be mined for use in the arts. They would, however, be beautiful ornamental or semiprecious stones. Two of these minerals are utahite and prosopite. The former resembles turquoise in composition, being a hydrous phosphate of alumina; the latter is a fluoride of alumina and lime. Both occur in choice shades of green, due usually to a small amount of copper compounds, and both are hard enough to take a handsome polish.

Utahite, so named by the writer in 1895, was discovered in Cedar valley, in a spur of the Oquirrh mountains, near Camp Floyd, Utah, in the previous year, by Mr. Don Maguire. It belongs to the mineral species variscite, but presents a new and peculiar form. Variscite usually occurs in crystals or incrustations; utahite forms compact nodular masses, ranging from the size of a walnut to that of a cocoanut. These occur in slaty layers in a crystalline limestone, and are generally surrounded with a brown ferruginous crust. In color, the interior mass is of various shades of bright green, generally a very vivid golden green or light emerald; and the nodules, cut across and polished, have been much admired and sought by collectors. The mineral is not very abundant at the locality, and can only be removed from the rock with care by the hands. Pieces could be easily cut for small objects, and would be extremely handsome for such uses, owing to the brilliant and delicate coloring. It has been used to some extent for ring stones, cuff buttons, seal rings, and other purposes as jewelry with considerable success.

Prosopite at first was supposed to be identical with utahite, but an analysis made by Mr. W. J. Hillebrand proved it to be a fluoride of alumina, known already as a rare species of mineral from Saxony, Germany, and from Pikes Peak, Colo., where it occurs, but without the rich blue-green color of that found in Utah. Here it was obtained by Mr. Josiah Beck in 1895 in the Dugway mining district, in Tooele county, in a region of low and desert hills. The mineral was not fully identified until 1899, when the analysis was made and the result published.[1] The prosopite is a beautiful stone, but whether it exists in sufficient amount to be of practical use has not yet been determined.

Anthracite.—There is a small but fairly constant sale in the coal region of eastern Pennsylvania of articles of ornament carved from anthracite coal, such as

[1] American Journal of Science, January, 1899, pages 53, 54.

inkstands, paper weights, etc. These are usually made partly polished and partly rough, so as to show a contrast between the two different kinds of black surfaces. They are sold almost entirely as local souvenirs to persons visiting that part of the country. The sale of such articles has been estimated for some years past at a total varying from $1,000 to $2,000.

Catlinite (*pipestone*).—This material, celebrated in Indian history and immortalized by Longfellow in "Hiawatha," is used to some extent for making ornaments and souvenirs that are sold to visitors in the region of its occurrence—Pipestone county, in southwestern Minnesota. It is not really a definite mineral species, but essentially an indurated red clay. Among the Indians it has long been held almost sacred as the material for making "pipes of peace." The principal locality where it is found was, and still is, visited by Indians from all parts of the country to obtain it for that purpose, and is still regarded by them as a kind of inviolable spot, where all have the right to come. The United States Government has very properly set apart the land on which the quarry exists as a small reservation, to secure this free right of access to all Indians forever. It is jealously guarded by the native tribes, and it is seldom that large pieces can be secured by white men; hence the supply is rather limited and is likely to remain so. The only large object ever made from this material was a mantelpiece, carved by an Indian artist, with designs from Hiawatha, which was exhibited in the Minnesota building at the Pan-American Exposition of 1901. It had been shown previously at the Columbian Exposition in 1893, and is now in the courthouse at Pipestone, Minn., in the room occupied by the Women's Historical Society, to which organization it belongs. The sale of ornaments and souvenirs made of catlinite is estimated at about $2,000 annually, for some years past.

Fluorspar (*Illinois*).—The old and celebrated "Shawneetown" region in southern Illinois has lately been yielding fluorite of remarkable beauty. In a lot of specimens recently sent to the writer for examination were cleavage pieces of much beauty from several of these localities, notably the Empire mines and Cave-in-Rock. From the former were large cleavages of rich reddish purple, and of the peculiar sea-blue of that region; in one case the general color was of the latter kind, clouded at points with the former—like the tint of a blue Alabashka topaz with included clouds of Uralian amethyst. Both the purple and the sea-blue varieties at times pass into almost colorless fluor. That received from Cave-in-Rock presents an octahedral cleavage, perfectly transparent and of amber yellow. A cubical crystal received from Rosiclare was pale bluish, becoming nearly colorless.

QUARTZ MINERALS.

Rock crystal.—Rock crystal is a variety of transparent colorless quartz, composed of nearly pure silica. While it is not rare as a mineral, yet it is seldom found in masses of large size. When so found, however, it is valuable for use in the ornamental arts. One or two localities in the Alps, that have been known and worked from Roman times, though very difficult and perilous of access, have furnished material for all the objects in European palaces and museums which have been carved from this substance. In Japan, too, large crystals were formerly obtained, from which were made the polished balls, so much prized by the natives, and afterwards by foreigners, who have now almost drained the country of them by purchase. The main supply in recent years has been derived from Madagascar and Brazil.

Within the last decade very fine rock-crystal masses have been obtained in the United States, especially in California. An important discovery was made in 1891–92 by Mr. James Blackiston, near Placerville, Eldorado county. Here, in a partly decomposed quartz vein, were found crystals ranging from small sizes up to masses of 80 or 90 pounds in weight. Some are clear and flawless, while others have the peculiar and beautiful marking known as "included phantoms." This feature has been caused by successive deposits, and is shown by the appearance of several crystals of identical form, one within another, each being outlined by a thin coating of some other mineral, which delicately colors the otherwise transparent quartz. These coatings in the California crystals are of rich green chlorite. Similar chlorite phantoms in clear quartz have since been found also in San Bernardino county, in the mountains of that name.

The most remarkable discovery of quartz in California, however, was made in 1897, in Calaveras county, at the old Green Mountain mine, in Chile gulch, near Mokelumne Hill. Here, in one of the ancient river channels filled with auriferous gravel and covered by an overflow of lava—a formation characteristic of that region of the state—was found a quantity of enormous quartz crystals, embedded in the old gravel. It is claimed that 12 tons were taken out in the years 1897 and 1898. One giant crystal, surrounded by an attached cluster of smaller ones, weighed over a ton. A number of the finest specimens were sent to New York, and splendid balls were cut from them by machinery especially constructed for the purpose. Two of these balls were a little over 7 inches across, but they are not absolutely flawless. A third, $5\frac{1}{2}$ inches in diameter, without a blemish, was valued at $3,000. The latter, and one of the other two, are in the Tiffany-Morgan collection at the American Museum of Natural History in New York; the other is in the Museum of the Jardin

des Plantes at Paris, with the collection of American gem minerals that was prepared for the Pan-American Exposition of 1901.

So far as the gravel deposit was explored, the crystals appeared to be strewn through it, and it would seem to contain a large amount of valuable material, although no work has been done there since 1898. Other localities in California where crystals weighing several pounds have been found are Drum valley, Threerivers, and Yokohl, in the neighborhood of Visalia, in Tulare county.

In Oregon, large transparent masses have been found near Bay City, but no particulars of their occurrence are given.

Some fine rock crystal occurs in North Carolina, in Chestnut Hill township, Ashe county, on a spur of Phoenix mountain, near Long Shoal creek. Here, at two or three spots not far apart, were found pieces up to 50 pounds in weight, and two very large crystals, of 188 and 285 pounds, respectively. A crystal ball, 5 inches in diameter, and a number of art objects, all of American workmanship, made from this material, were shown at the Columbian Exposition at Chicago in 1893. Another find in North Carolina was reported in 1896, from Elkin, in Surry county, by Mr. R. M. Chatham, who described crystals up to 40 pounds in weight. Some large crystals are also known to have been found in South Carolina, and it is probable that much rock crystal adapted for use in the arts, exists in the mountain regions of the South.

Colorado has furnished some fine material, especially that from Mt. Antero, Chaffee county. A polished ball, 6 inches in diameter, from the summit of this mountain was exhibited at the Columbian Exposition.

A find of considerable quantity was reported in 1896, at Cheyenne pass, Wyoming, about 18 miles west of Cheyenne city, but no development at that point appears to have been undertaken.

The quartz crystals of Hot Springs, Ark., have been known for many years and furnish a constant source of business to the farmers of the surrounding country, who collect them and bring them in by the wagon load to sell to local dealers and to tourists. These crystals are not large enough to yield art material, but they are beautiful as specimens, either as single crystals or more frequently in groups. It is estimated that in the year 1896 no less than 15,000 pounds were gathered in Montgomery, Saline, and Garland counties and sold in the city of Hot Springs for $5,000.

Colored varieties.—Among the colored varieties, besides amethyst, of crystalline quartz suitable for use as precious or semiprecious stones, two are important—smoky quartz and rose quartz. Both are found at various points in the United States and have been mined more or less during the past ten years, although there is no large or continuous supply.

Smoky quartz.—The most noted place in which smoky quartz occurs is at and near Pikes Peak, Colo., where it is abundant in fine crystals, in a coarse granite, associated with the beautiful crystals of green feldspar (amazon stone), for which that locality is famous. It is found also at Mt. Antero, in Colorado, where the smoky quartz obtained in 1891 yielded one of the finest faceted stones in the world, measuring 3½ inches in length. It was cut and exhibited at the Columbian Exposition. Much of the material from Pikes Peak is sent abroad for cutting, and returned to be sold at Denver and Colorado Springs, Colo., at Hot Springs, Ark., and other interior resorts, as jewelry to tourists. The annual sales amount to about $10,000, three-fourths of which is for cut stones and one-fourth for specimens.

Large crystals, up to 4 and 5 inches in diameter, have been collected at Brandy creek, in Lemhi county, Idaho. They have been found, too, at Three Mile Gulch, near Helena, Mont., and a gigantic crystal, nearly 2 feet long and weighing 93½ pounds, was found in 1900, on Clear creek, Jefferson county, Mont., by Mr. E. P. Chisolm. Crystals have also been reported at points in South Dakota. A considerable quantity occurs in connection with the colored tourmalines in southern California, both at the San Jacinto mine in Riverside county and those at Mesa Grande in San Diego county.

In the East very fine smoky quartz has been found in Maine and in North Carolina, as well as at some other points. The specimens from Maine are particularly beautiful. Crystals of 40 pounds in weight were reported in 1896, by Mr. R. M. Chatham, from a locality near Elkin, in Surry county, N. C., and it was already well known in the neighboring counties of Alexander, Burke, and Iredell. In Connecticut, at New Milford, some 200 pounds of smoky quartz, worth over $100, was taken out in 1898. But the most valuable yield has been in Oxford county, Me., where as much as 3 tons of crystals were reported by Mr. T. F. Lamb, of Portland, as mined in 1897, on Mt. Apatite. Much has been taken out since, including one perfect crystal 12 pounds in weight, and a polished ball 3 inches in diameter has been cut from material obtained here.

Rose quartz.—The delicate pink variety of quartz known as rose quartz has long been obtained at several points in New England, especially at Albany, Stow, and Paris, in Maine; at Southbury, in Connecticut; also at Bedford, in Westchester county, N. Y. Though a beautiful material, it had been little used in the arts or as a gem until quite recently, when it was tried with some success. In general, and particularly in the case of the specimens from the localities in Maine, the tint varies greatly from an almost colorless variety, sometimes opalescent, to pale pink, salmon, and deep rose. When cut into double *cabochons*, or balls, it sometimes shows the asteria effect, like a star sapphire. Very fine, rich-colored pieces, partly opalescent and in size up to

4 or 5 inches in diameter, have been obtained at Round mountain, near Albany, Me., and a ball of 2½ inches across, with other cut objects from this locality, were shown at the Columbian Exposition.

Rose quartz occurs also at Acworth, N. H., in the celebrated beryl locality, and a large block of this material, some five feet square by half that thickness, has been set up as a monument in Franklin, N. H., to the late Walter Aiken, of that place. The mass is somewhat fissured, however, and rose quartz is liable to fade in the sunlight, so that neither in texture nor in color is it adapted for monuments or other use out of doors.

In 1894 the occurrence of rose quartz in Iredell and Cabarrus counties, N. C., was announced by Prof. T. K. Brunner. In 1895, 50 tons of it were mined at Theresa, in Jefferson county, N. Y., and its presence was noted in Colorado by Mr. E. H. Saltiel, at the headwaters of Currant creek, in Park county. In the same year Messrs. M. Braverman and W. H. Smith described several places where it occurred in the neighborhood of Visalia, in Tulare county, Cal., especially on the Yokohl river, where about $150 worth was then taken out. It exists in some quantity, and of excellent color, at Yokohl and Threerivers, in the same county, and probably at other points in that section.

By far the most extensive occurrence, however, is in the Black Hills of South Dakota. Specimens were first brought in by Prof. W. P. Jenney on his exploring expedition in 1876, and a fine display of it was made in the South Dakota building at the Columbian Exposition of 1893. The exact locality is near French creek, 6 miles east of Custer, in the county of that name. Here it exists in great quantity and of fine quality, outcropping along a ledge for 500 feet in a vein varying in thickness from a few feet up to 60. The color, as usual, ranges through many shades, from faint pink or even white, to the tint of a ripe watermelon, and in places alters completely within a few inches. Contrary to the general opinion, there is no evidence of its fading by exposure to light, for outside portions, and even rolled bowlders, show in some cases a fine deep coloring. Thus far the mining has been carried on mainly by hand, much in the nature of quarrying. About three-fourths of the stone removed is rejected as lacking color; the rest is sorted and sold according to size and color, chiefly to dealers and collectors, at prices ranging from 5 to 25 cents a pound. One mass weighing over a ton was recently sold to be cut into table tops, 30 by 36 inches in size, which were sent to Paris to fill an order. The production reported to the United States Geological Survey amounted to 4 tons in 1902.

Amethyst.—Amethyst is a variety of quartz of a deep purple or bluish violet color, shading almost to pink. Like ordinary quartz, it is composed of silica, and the coloring is due to the presence of oxides of manganese and iron. Its hardness is about 7, and its specific gravity is slightly above 2.65.

Fine gem material has been found in the United States, though nowhere is it mined with any regularity. The localities from which the finest specimens come are in Maine, Pennsylvania, North Carolina, southern Virginia, and northeastern Georgia, and several discoveries have been made recently in the West. The main developments within the last ten years are the following:

Deer Hill and Stow, in Maine, were noted localities some time ago, but have not yielded much lately. At Denmark, however, in the same state, Mr. G. R. Howe obtained many fine crystals in 1894, and had a number of gems cut that were very richly colored—equal to any from the Ural mountains.

Another old locality was Upper Providence township, in Delaware county, Pa. Here, in 1894, a large amount of amethyst was obtained that yielded gems of the finest quality, one of which was of 33 carats; and another, still larger, is in the Lea collection in the National Museum at Washington.

Virginia has only recently come into notice as a possible source of amethyst production. In 1896 its occurrence, in beautiful crystals, was announced at two points in Goochland county, by Mr. G. L. Chase, and also near Lovingston, Nelson county, by Mr. Benjamin Dillon. In 1902 a promising locality was discovered and opened in Amherst county, near Lowesville.

North Carolina has for years yielded more or less amethyst at various points in Burke, Catawba, Iredell, Lincoln, Wake, and other counties. In 1901 mining was begun in Macon county, on Tesanty creek, where a large vein traversing a decomposed granite had been exposed by a landslide. Several thousand dollars' worth of material was taken out, as rich and fine in quality as any ever found in the United States.

Amethyst of excellent quality has been occasionally found in Anderson county, S. C., in Hall and Rabun counties, Ga., and at Amethyst mountain, in Gillespie county, Texas.

The western sources of production are chiefly in Montana. In 1895 a crystal weighing 12 pounds was found at Granite, and in 1900 remarkable discoveries were made in Jefferson county, some 22 miles southeast of Butte, by Mr. A. P. Pohndorf. Here amethyst occurs in fine crystals, curiously mingled with quartz both colorless and smoky. Crystals of black tourmaline so penetrate the quartz as to render it opaque. The amethyst itself is free from these inclusions, though sometimes it forms parts even of the same crystals.

In Colorado, amethyst is reported from Cripple Creek and from localities in Park and Mineral counties, but no special data have been given as to these occurrences.

Good material has been brought from two or three points in Alaska, but there has been no development as yet.

Quartz pebbles.—Natural rolled pebbles of quartz, of various colors, are often beautiful, sufficiently so at times to be applied to some uses in the arts or

for cheap jewelry. At many points along the Atlantic coast, visitors to the seaside resorts gather pebbles of attractive aspect, especially those of colorless transparent quartz, and sometimes have them cut as souvenirs. These are the so-called Cape May diamonds, and there is quite an industry at many resorts in gathering pebbles to cut for gems, seals, etc. A good deal of fraud is also practiced upon visitors, all manner of ornaments being sold as material found in the vicinity. At Narragansett Pier, R. I., some local dealers and lapidaries have been known to sell foreign-cut quartz, cairngorm stone, topaz, crocidolite, Ceylonese moonstone, and even glass as stones from the beach. In some cases pebbles found by visitors and entrusted to lapidaries for cutting have been replaced by cut stones imported from Bohemia, Oldenburg, and the Jura, where cutting is done on such a large scale and at such low wages that the stones can be brought here at one-tenth of the cost of cutting, the material itself, in the case of quartz, having but small value. The annual proceeds from the sale of cut stones, and the money expended in cutting them at these and other resorts throughout the country, may amount to $20,000 or more a year, and the sale of specimens to a like sum.

Another ingenious fraud has been practiced at Hot Springs, Ark., where clear, rolled pebbles of colorless quartz, found on the banks of the Ouachita river, are in special demand, being more valued for cutting than the crystals of the vicinity, because of a mistaken idea that they will cut into clearer gems. Fine pebbles of this kind are scarce, and so they have been artificially imitated by putting a number of crystals into a box, which is kept revolving by waterpower. In a few days mutual attrition has rolled and roughened the crystals into beautiful pebbles—so beautiful, indeed, that an expert can distinguish them from the real ones by their more perfect whiteness of surface.

Along the coast of California and Oregon there are various localities where many very attractive pebbles of chalcedony, agate, etc., are found. The principal beaches are at Crescent City, at the northern extremity of California; Pescadero, some 28 miles west of San José; and Redondo, a few miles south of Los Angeles. These pebbles are very abundant and in great variety, and are much sought by visitors. Many are put up and sold in bottles of water, to preserve their bright colors and markings and their translucency; and many are drilled and strung to make chains and similar fancy ornaments. Some of those at Pescadero are little hollow geodes of chalcedony, occasionally an inch long, inclosing a liquid with a moving bubble. These little natural-sealed flasks are found also on the beach at Tampa, Florida.

There are likewise many inland localities—several in California, especially on the shore of Lake Tahoe; also in Colorado, and the beaches of Lake Superior—long famous for their agate pebbles, chlorastrolites, etc.

One special use of quartz pebbles in ornamental art work should be here alluded to. On Plum Island, in Long Island sound, there are quantities of pebbles of colored quartz—amethystine, smoky, yellow, etc.—brought down by glacial action from the crystalline rocks of Connecticut and rolled and rounded on the island beach. These have been used in a very effective manner, in the same way as rounded pieces of colored glass, by leading them for screens, shades, etc., to show their tints by transmitted light. This application was introduced about 1897, by Mr. Louis C. Tiffany, of New York.[1]

Agate and chalcedony.—These minerals are forms of quartz (silica), but differ from those previously noted in being noncrystalline, or at least the crystalline structure, if present at all, is only discernible by the microscope. They are also never transparent, but vary from translucent to nearly opaque. With the exception of colorless chalcedony or white carnelian, they are variously and often richly colored by metallic oxides, principally those of iron and manganese, and furnish a number of semiprecious stones that have long been favorites in jewelry and art work.

There are many localities in the United States where handsome agates and chalcedonies occur, and some of these may hereafter be commercially developed. But with the exception of the little local trade in agate and chalcedony pebbles, already mentioned as carried on at certain of the beach resorts on the Pacific coast (see quartz pebbles, above), and likewise to some extent with the agate pebbles of Lake Superior, there is hardly any continuous production or sale. At one point, however, a deposit of agate occurs that is unequaled in the world, and deserves special mention. This is the agatized forest, or Chalcedony Park, of Arizona, where an area of many square miles is strewn with logs and trunks of an ancient growth of trees, now completely altered to silica, and stained with the richest and most varied hues by the oxides above named. Silicified wood is by no means uncommon, but it rarely presents such beauty of coloring as here, where fallen and broken trunks many feet in length and ranging up to as much as 4 feet in diameter, with the woody structure perfectly visible, are converted into agate and chalcedony of every mingled shade of red, brown, and purple. When polished this makes one of the most beautiful and interesting ornamental stones in the world, and has attracted great admiration abroad as well as in this country. Splendid exhibits of it in the form of table tops, clock bases, pedestals for statuary, and many kinds of minor articles, have been made at the Columbian and Pan-American Expositions and at the Paris Exposition of

[1] United States Geological Survey, "Mineral Resources of the United States," 1887, page 14.

1900. These have been shown by the Drake Company, of Sioux Falls, S. Dak., who obtained a large amount of the material, and erected machinery and polishing works at that place, operated by waterpower, and succeeded in producing beautiful results. Previously there had been no polishing works in this country that could deal with large pieces of a material as hard as quartz.

The locality is in Apache county, Ariz., a few miles south of the Southern Pacific Railroad from Adamana station, not far from the town of Holbrook. It consists of three open valleys or eroded areas among a wilderness of mesas and buttes. The logs, more or less shattered into pieces and fragments or cylindrical cross sections, lie along these valleys by thousands, having been washed out of the rather soft sandstone that formerly covered the whole region, and which still remains in the intervening hills and buttes. At some points the logs may be seen in place in the sandstone, especially at the celebrated "chalcedony bridge," where a large trunk spans a gully worn in the side of a small hill. Geologically these beds belong to the Triassic formation, equivalent to the brown and red sandstones of New Jersey and the Connecticut valley. But the trees grew at a somewhat earlier time, and were overthrown and buried in the sandstone when that was laid down by an invasion of the Triassic sea. These points have been fully determined by Prof. Lester F. Ward, of the United States Geological Survey, in two visits to the region in 1899 and 1901.

This beautiful material exists in very large quantities, but since access has been made more easy from the railroad, tourists, vandals, and speculators have been coming in and there has been danger of seriously despoiling one of the most remarkable natural curiosities in the country. Some years ago the legislature of Arizona petitioned Congress to set apart the Chalcedony Park as a reservation, and this course was strongly recommended by Prof. Lester F. Ward, after his recent visits. Of course, under Government control, a judicious and reasonable removal of material for use in the arts is now permitted; and under such supervision a permanent supply for legitimate purposes will be assured, but spoliation and speculation will be properly prevented.

The yield reported in the last five years has risen steadily; it was $2,000 in 1898, $3,000 in 1899, $6,000 in 1900, and $7,000 in 1901 and also in 1902.

Chrysoprase.—Another semiprecious stone which has been developed in the United States within the past decade is chrysoprase, a chalcedony of a light green color, caused by the presence of oxide of nickel. This stone has been highly valued for centuries, but is of rare occurrence, and most of that used in jewelry and in the arts has been obtained from Silesia. Its existence in North America had been recognized at some points before, but the only promising locality was at Riddles, Douglas county, Oreg. Mr. George W. Smith, a surveyor, obtained specimens in Tulare county, Cal., as far back as 1878. These he submitted to experts, who pronounced them to be true chrysoprase. The first who positively identified them as such, by actual determination of the nickel oxide, was Mr. M. Braverman, of Visalia, Tulare county, who is well known for his enthusiasm in locating and collecting California minerals. From that time specimens were gathered and sent quite widely to museums and cabinets; but not for some years was its commercial value appreciated. When that became known, systematic development was attempted, the neighborhood was prospected, and other occurrences discovered, so that now there are not fewer than five localities in Tulare county where chrysoprase is known to occur. The first of these to be discovered was the one at Venice Hill, 12 miles northeast of Visalia; the others are on Stokes mountain, on the Tule river, on Deer creek, and at Lindsay, 16 miles south of Visalia. Mr. Braverman has been active in the search for these localities, and has presented to the California State Mining Bureau a very fine specimen from the last-named place. The veins which it forms are of no great thickness, and much of the material is flawed and cracked, or too pale to be valuable. Still a large quantity of fine chrysoprase has been obtained and cut, from these several localities, especially the last two and the first. The total production for several years did not much exceed $100 annually, but since a new company took up systematic work two years ago the yield rose to $1,500 in 1901, and $15,000 in 1902. Most of the material is cut into squares, ovals, etc., for rings and studs, and into small pieces of various shapes for inlaying as mosaic.

Within the past year a promising locality has been discovered in North Carolina, at Morganhill, in Buncombe county, some 16 miles from Asheville. Here it occurs in several parallel seams or veins quite near to each other; the color is pale at the surface, but becomes deeper below. No extensive work has yet been done here, although some very rich green material has been cut and placed on the market, and the outlook is favorable.

Moss agate.—The name "moss agate" is applied to a variety of translucent chalcedony, usually nearly colorless, that is penetrated by minute branching or "dendritic" (tree-like) crystallizations of oxide of manganese or of iron, the former black, the latter brown or reddish. It has long been a favorite semiprecious stone in Europe and the East, but large pieces are rare. Small rounded nodules of it are abundant at various places in the West, particularly in Wyoming. In 1893 large masses were found near Hartville, Wyo., occurring in a vein 8 or 10 inches thick in limestone. Slabs of 2 or 3 feet in length could be taken out, accord-

ing to Mr. H. A. Crane, of Hartville, who described its occurrence, and table tops made of it were shown in the Wyoming section of the World's Columbian Exposition at Chicago. The translucent white slabs, with moss-like markings in black, are very beautiful.

Two other localities in which fine moss agate has been found are reported in Wyoming, one 47 miles and the other 75 miles northwest of Cheyenne. No important developments, however, appear to have been made at these points.

TABLE 4.—DETAILED SUMMARY: 1902.

	United States.	California.	Montana.	New Mexico.	All other states and territories.[1]
Number of mines or quarries	46	31	3	8	4
Number of operators	460	47	3	60	350

[1] Includes operators distributed as follows: Arkansas, 50; Arizona, 46 (1 mine); Colorado, 25; Idaho, 1; Maine, 13; Minnesota, 110; Nevada, 8 (1 mine); New Hampshire, 10; North Carolina, 18 (1 mine); Pennsylvania, 55; South Carolina, 5; South Dakota, 3; Virginia, 3; Wyoming, 3.

TALC AND SOAPSTONE

TALC AND SOAPSTONE.

By Joseph Hyde Pratt.

Talc and soapstone have assumed a very important place among the minor minerals, and in respect to the value of the production are near the head. This is due not so much to the variety of uses to which they are put as to the very remarkable growth in the utilization of talc in the manufacture of paper, for nearly two-thirds of the value of the production in 1902 was used for this purpose. Statistics for talc and soapstone include a small production of serpentine and the production of pyrophyllite, both of which are mined and used for the same purposes as those for which talc is employed.

In treating the statistics of the talc and soapstone mining industry it is necessary to include also the statistics of the manufacturing processes which are conducted at the mines under the same management, as the financial and other details are inseparable. This method has been customary since the census of 1860, which was the first census to give statistics for this industry.

Table 1.—*Comparative summary: 1860 to 1902.*

	1902	1889	1880	1870[1]	1860

Cost of supplies and materials	$125,932	$35,454	$18,201	$98,325	$10,425
Product:[7]					
Quantity, short tons	97,563	36,461	12,651	[2]	[2]
Value	$1,138,167	$475,878	$121,395	$189,115	$27,600

[1] Classification was "soapstone stoves, fireplaces, sinks, and cisterns."
[2] Not reported.
[3] Establishments.
[4] Not reported separately.
[5] Salaries included in wages.
[6] Foremen included in wage-earners.
[7] The United States Geological Survey reports 97,954 short tons, valued at $1,140,507, which includes 391 short tons of soapstone, valued at $2,340, used as a mineral pigment and so reported by the Census.

The industry, as will be seen by the table, increased from a product in 1860 valued at $27,600 to one in 1902 valued at $1,138,167. From 1870 to 1880 there was a falling off in value of $67,720, although there were 5 more mines or establishments in operation and 104 more employees engaged in the work. This probably can be accounted for by the fact that a number of new properties were being opened and developed, and this development required a large increase in the number of employees without resulting in production for the current year.

Only the statistics for New York and North Carolina can be given separately, as there were not more than 2 producers in any of the other states. There were 20 mines in operation in the United States during 1902, of which 6 were in North Carolina; 4 in New York; 2 each in Maryland, Pennsylvania, and Virginia; and 1 each in California, Georgia, Massachusetts, and New Jersey. Thirteen mines were reported idle—1 each in California, Maryland, Massachusetts, North Carolina, and Ohio; 2 each in New Hampshire and Virginia; and 4 in Georgia.

Capital stock of incorporated companies.—Of the 20 mines reported, 13 were operated by incorporated companies, 4 by individuals, and 3 by firms. The details of the capital stock and funded debt authorized and issued by the 13 incorporated companies are shown in the following table:

Table 2.—*Capitalization of incorporated companies: 1902.*

	United States.	New York.	North Carolina.	All other states.[1]
Number of incorporated companies	13	4	5	4

[1] Includes operators distributed as follows: California, 1; Pennsylvania, 1; Virginia, 2.

Five of the incorporated companies were in North Carolina, 4 in New York, 2 in Virginia, and 1 each in California and Pennsylvania. The capital stock and funded debt of the 4 New York companies constituted 79.5 per cent of the total. The par value of the capital stock issued was 90.9 per cent of the total par value authorized. The bonded indebtedness was 8.4 per cent of the capital stock and funded debt. The dividends paid amounted to 1.3 per cent of the total stock issued and 5.1 per cent of the total stock on which they were declared. Sixty-five per cent of the total amount paid in dividends was declared on preferred stock and 35 per cent on common. Of the total dividends 73.7 per cent was paid on the stock of the New York mines and 26.3 per cent on that of the mines in Virginia.

Employees and wages.—In considering the question of employees and wages, it is to be observed that the talc and soapstone industry is a composite one of mining and manufacturing. There are two principal kinds of manufacture: (1) The grinding of talc into flour, after which it is packed in bags preparatory to shipment, and (2) the sawing and finishing of soapstone into slabs, mantelpieces, laundry tubs, etc. Thus it can readily be seen that more employees are required, in proportion to the tonnage of the mineral mined, in an establishment where the higher grades of manufactured articles are made than in a plant where the mined talc is merely ground. This will explain the large number of employees in proportion to the tonnage in "all other states," because in these the soapstone mined is largely converted into manufactured articles, this being especially true of Virginia.

The number of salaried employees was 75, or 8.9 per cent of the aggregate average number of all employees, which was 846, and they received in salaries $63,713, or 18.6 per cent of the total salaries and wages, which amounted to $342,796. The number of wage-earners was 771, who received $279,083 in wages, which were 91.1 and 81.4 per cent, respectively, of the total number of employees and total wages. There were on an average 38.5 wage-earners to a mine. Of the states, the statistics of which are shown in detail, New York had 21.1 per cent of the wage-earners, and they received 30 per cent of the wages paid. North Carolina had 8 per cent, and they received 7.7 per cent of the wages.

Of the 771 wage-earners, only 98, or 12.7 per cent, worked below ground, the remaining 673, or 87.3 per cent, being employed above ground. Some of these, however, were employed in cleaning and preparing the talc and soapstone for market, while all the underground wage-earners were directly employed in mining the talc. Besides the number of wage-earners mentioned above, there were 9 foremen included among the salaried employees, who worked below ground.

Of the 771 wage-earners, 411, or 53.3 per cent, are classified as "miners or quarrymen and stonecutters;" of these 73, or 17.7 per cent, were employed in New York; 57, or 13.9 per cent, in North Carolina; and 281, or 68.4 per cent, in "all other states." In New York, 69 miners were employed underground and only 4 were reported as working above ground. In North Carolina, 8 miners were reported as working underground, and in "all other states" only 3 were so reported.

The daily rates of pay of the wage-earners, as given in Table 5, varied from 50 cents to $3.49 per day. Nearly one-half of the total number of all classes of wage-earners, or 46.8 per cent, received from $1 to $1.24 per day; 132, or 17.1 per cent, were paid from $1.25 to $1.49 per day. The highest rate of pay was received by those classified as "all other wage-earners," 16 of whom were paid from $3.25 to $3.49 per day, these being employed in the manufacture of the more intricate articles made from soapstone.

Of the 411 miners or quarrymen, 249, or 60.6 per cent, received only from $1 to $1.24 per day, this being due largely to the fact that most of these workmen were employed in the southern mines, where the rate of wages was much lower than it was for the same class of labor either in the North or East.

The average number of wage-earners employed during each month is also shown in Table 5. The busiest months for the industry were August, when an average of 826 employees were at work, and September, when the average reached 841. The month with the smallest average was November, with 705. In New York the greatest average number employed was 168, that number working in January and December. In North Carolina the greatest average was 85, employed in July, August, and September.

Supplies, materials, and miscellaneous expenses.—The amount, $125,932, reported as paid for supplies and materials was the principal item of expense, next to wages. Of the amount, $80,136, reported for miscellaneous expenses, $31,364, or 39.1 per cent, was expended for royalties and rent of mine and mining plant, and $48,772, or 60.9 per cent, for rent of offices, taxes, insurance, interest, and other sundries.

Mechanical power.—Of the 20 operators, 16 reported primary power aggregating 3,945 horsepower. Of this, 2,700 horsepower, or 68.4 per cent, was supplied by water wheels; 1,235, or 31.3 per cent, by steam engines; and 10, or three-tenths of 1 per cent, by gas or gasoline engines. There were reported in addition 3 electric motors having a capacity of 225 horsepower. Of the 2,700 horsepower furnished by water wheels, 1,650, or 61.1 per cent, was used in New York; 630, or 23.3 per cent, in North Carolina; and 420, or 15.6 per cent, in "all other states." Of the 1,235 horsepower generated by steam, 530, or 42.9 per cent, was employed in New York; 70, or 5.7 per cent, in North Carolina; and 635, or 51.4 per cent, in "all other states." The 10 horsepower generated by gas or gasoline engines was used in California. The electric motors were reported from Virginia.

Production.—The total production of talc and soapstone in 1902 was 97,563 short tons, valued at $1,138,167, of which the state of New York, with 4 establishments, produced 71,100 tons, or 72.9 per cent, and North Carolina 5,238 tons, or 5.4 per cent, leaving 21,225 tons, or 21.7 per cent, for the 7 other states. In the value of the production New York is credited with 54.1 per cent of the total value, North Carolina with 7.8 per cent, and the 7 other states, collectively, with 38.1 per cent. In order to show the growth of the talc and soapstone industry in the United States since 1880, there is given in Table 3 the production of these minerals as reported by the United States Geological Survey since that year:

TABLE 3.—*Production of talc and soapstone: 1880 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Quantity (short tons).	Value.	Average value per ton.
1880	12,651	$121,395	$9.60
1881	12,000	135,000	11.25
1882	12,000	165,000	13.75
1883	14,000	225,000	16.07
1884	20,000	310,000	15.50
1885	20,000	310,000	15.50
1886	24,000	350,000	14.58
1887	27,000	385,000	14.26
1888	35,000	460,000	13.14
1889	36,461	475,878	13.05
1890	55,024	641,505	11.66
1891	69,568	737,049	10.59
1892	65,833	909,934	13.82
1893	56,932	658,503	11.57
1894	63,050	836,385	13.27
1895	60,735	637,392	10.49
1896	68,272	753,508	11.04
1897	78,932	762,565	9.66
1898	76,587	698,542	9.12
1899	79,420	768,955	9.68
1900	91,443	883,041	9.66
1901	97,843	908,488	9.29
1902	97,954	1,140,507	11.64

Since 1880 the average price per ton has ranged from $9.12 in 1898 to $16.07 in 1883. In 1902 the prices reported as received for the talc and soapstone products varied from $2.25 for material sold in the rough as quarried, to $31,025 received for manufactured articles. This wide variation in price is readily explained by the various uses to which talc and soapstone are put, and to the amount of work that is required in preparing the manufactured articles for market.

The imports of talc, 1880 to 1902, inclusive, principally from France and Italy, as published by the United States Geological Survey, are shown in the following table:

TABLE 4.—*Talc imported into the United States: 1880 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States."]

YEAR.	Quantity (short tons).	Value.	YEAR.	Quantity (short tons).	Value.
1880	(1)	$22,807	1892	531	$5,546
1881	(1)	7,331	1893	1,360	12,825

1891	81	1,121			

[1] Not reported.

The detailed statistics of the industry for 1902 are given in Table 5.

DESCRIPTIVE.

The name talc has been used very commonly, and yet erroneously, for a number of minerals which are similar to it in physical properties, but distinct mineralogically. Commercially, the name talc is usually applied to the fibrous and foliated varieties, which are the purer forms, and the name soapstone confined to the massive varieties. Mineralogically, the name talc refers not only to the foliated and fibrous varieties, but also to those which are compact, and soapstone or steatite is simply a variety of this mineral. Talc may be considered as occurring in the varieties, foliated and massive, with a third division known as fibrous talc, which is usually called pseudomorphous, as it has generally resulted from the alteration of the mineral enstatite. The foliated talc is the most valuable, being pure and very free from grit, so that it is suitable for use in the manufacture of talcum powders, etc. Occasionally this variety is so compact that it can be used in the manufacture of tailors' pencils, when it commands the highest price paid for any talc. Certain varieties of the massive talc are also pure enough to be ground into a flour talc, but the greater portion is used in the manufacture of soapstone articles.

The properties of talc (exclusive of soapstone) that make it suitable for the purposes for which it is used are its extreme softness, its purity or freedom from grit, its stability, and its smooth, slippery surface. Since the minerals serpentine and pyrophyllite closely approximate many of these properties, they are used to some extent for the same purposes. This is true especially of the latter, which can be used for many of the purposes for which flour talc is employed.

Occurrence.—Talc is found very commonly throughout many of the states, and in small quantities it is very widely distributed. The steatite variety occurs more frequently in commercial quantities, but it can be worked profitably only when it is located most favorably with regard to transportation facilities and in proximity to a market for the manufactured articles. In a number of states this variety is quarried and used for chimneys and fireplaces by the inhabitants of the district in which it occurs, but it is impossible to tell exactly how much is used in this way. It has been roughly estimated that in the mountains of North Carolina from 25 to 50 short tons per year are so used.

Large deposits of foliated talc have thus far been found only in North Carolina and New York, and in both cases they are associated with limestone. Small amounts of this variety of talc are found associated with the basic magnesian rocks extending from Alabama to Canada, but in no case has it been found in commercial quantity. Where, however, the pyroxenite variety of these basic magnesian rocks has been converted into the secondary rock composed almost entirely of the

steatite variety of talc, it makes a deposit of commercial value if favorably located, as mentioned above.

Talc has been mined in California, Georgia, Maryland, Massachusetts, New Hampshire, New Jersey, New York, North Carolina, Pennsylvania, Vermont, and Virginia. In 1902 it was mined in all these states except New Hampshire and Vermont. The California "talc product" that was put on the market in 1902 was not talc, but a variety of serpentine obtained from Santa Catalina Island, Los Angeles county. Recently, however, a deposit of talc was discovered in Tulare county, near Lindsay, about 2½ miles east of the railroad, where it occurs in lenses of from 6 to 8 feet in width and 100 or more feet in length. Since no good talc deposits are being worked on the Pacific coast, this deposit is worthy of investigation as to its commercial possibilities.

The deposits of Georgia and North Carolina are somewhat similar in their occurrence, and are probably parts of the same belt, although the Georgia talc is more compact and not so fine in quality. In Georgia the principal mining has been done in Murray county. At least one-half of the talc mined in this state is put on the market in the form of ground talc.

The deposits of North Carolina are found in Swain and Cherokee counties, and that portion of the belt in Swain county furnishes the most valuable talc that is produced in the United States, and in many respects is a unique occurrence of this mineral. The quality of this talc is such as is used in the manufacture of tailors' pencils, etc., and for which there is a larger demand than can be met. All the rest of the North Carolina talc is ground to flour, and most of it is used in the manufacture of toilet powders. In Moore county occur the pyrophyllite (soapstone) deposits, which have been mined quite extensively, the product being used for various purposes. None of it is as good quality as the genuine talc, nor does it command as high a price. For foundry purposes, however, as far as can be judged, it ought to be as satisfactory as the other.

The Massachusetts talc deposits are not very numerous, and the only one worked in 1902 was near Dalton, Berkshire county. The talc is of the foliated variety, and all that was mined was ground to flour talc.

The deposits of talc in Maryland and Virginia are of the steatite variety, and nearly all mined in these states is used for manufactured articles. A very small amount has been ground to a flour talc. A fibrous talc has been obtained in some quantity in the vicinity of Wiehle, Fairfax county, Virginia.

Soapstone deposits occur on both sides of the Delaware river, being found in Warren county, N. J., and in Northampton county, Pa., in the vicinity of Easton. The general width of this soapstone belt is from 500 to 600 feet, and the mineral is obtained usually by quarrying. Practically all of the Pennsylvania and New Jersey talc or soapstone is put on the market in the form of a ground product, most of which is used in the manufacture of paper.

St. Lawrence county, N. Y., is the scene of the largest talc industries in this country. The talc is of the fibrous variety, and is used almost entirely in the manufacture of paper. There are about twelve mines in this talc region, and they are located near Talcville, St. Lawrence county, and Littleyork, Cortland county. Since the consolidation of a number of the smaller properties the mining and manufacture of ground talc has been carried on more systematically and on a larger scale, thus increasing the production of talc in this state and decreasing the cost.

About 3 miles southeast of the village of Rochester, Vt., are old talc mines which were worked rather extensively during 1865–66. These are now being reopened and developed, and the material will be put on the market as ground talc.

There were no new deposits that produced talc during 1902, although some work was done in investigating deposits, most of the deposits investigated, however, proved to be of little or no commercial value, being for the most part of the steatite variety.

Methods of mining, manufacturing, and cleaning.— The mining of talc is either (1) by means of open cuts and pits, (2) by a system of shafts or tunnels and drifts, or (3) occasionally by a combination of both cuts and shafts. The mining of the soapstone (steatite) is largely by the first method. Mining by shafts, tunnels, and drifts is confined to the foliated and fibrous varieties of talc. In New York the method of mining is practically the same at all of the mines. Inclined shafts are sunk, following the dip of the country rock, which is first gneiss, and then massive white dolomite, as the beds of talc are approached. These rocks stand very well, so that timbering is required only occasionally. When the shafts reach the beds of talc, drifts are run along the strike of the deposit. On account of the compactness of this talc, blasting is usually necessary in removing it. As the talc comes from the mine it varies in size from particles no larger than dust to masses two feet or more in length, and it is conveyed in hand cars to the mills, where it is pulverized. The larger masses are broken with sledges and then passed through Blake crushers and conveyed by a belt to a pair of slightly corrugated steel rolls, which reduce the talc to small pieces, one-fourth inch or less in length. From the rolls the crushed talc is carried by an endless belt conveyor to bins on the top floors of the mills, and then it is conveyed automatically into Griffin mills on the floor below. A draft of air is forced through the mill, and as the talc becomes fairly fine it is blown through an opening and falls to the floor below. It is returned to the second floor and conveyed into large hopper shaped bin cars, from which it is dropped into Alsing cylinders, in which is a quantity of waterworn quartz pebbles, 2½ inches or less in diameter. As the cylinder revolves

the constant pounding and rubbing of these quartz pebbles on the talc completely pulverize it. From this cylinder the talc passes through a grating, thus becoming separated from the quartz pebbles, and is conveyed automatically into a bag filling machine, where it is bagged and weighed, ready for shipment.

Talc mining in North Carolina does not present any serious difficulties, as the deposits do not extend to any great depth. The presence of water in the mines in the lowlands occasionally causes considerable expense and loss of time. Most of the mines thus located have been worked by means of open pits, which during a period of heavy rain have to be abandoned on account of being flooded. Although some of the deposits, especially those on the hillsides, can be worked advantageously by means of open pits, the majority of them are worked to the best advantage when shafts or tunnels and drifts are used. Little blasting is necessary at any of the mines, as the talc can usually be removed readily by pick and gad. As the rough blocks of talc are taken from the mine they are hand cobbed if necessary and sorted into three grades. The larger pieces are cleaned by rubbing them with steel brushes, and the smaller ones by a founder's scouring machine. They are then dried by being spread over a floor of steam pipes, which are kept at a temperature of 212° F. When these pieces are dry they are crushed and ground by means of crushers, rolls, and pulverizers, and the foreign material removed by screening. It is then further ground in buhrstone mills, similar to those used in grinding wheat, and passed through bolting cloth, which makes the final product nearly uniform in grain. This ground product is handled very much like flour, and in filling the bags with the flour talc, an ordinary flour packer is often used.

In Maryland, New Jersey, Pennsylvania, and Virginia, where it is principally the steatite variety of talc that is produced, the mining operations are carried on almost entirely in very large open cuts and pits. The preparation of the ground talc from the New Jersey and Pennsylvania mines or quarries is a process similar to that described above. In Virginia, where the soapstone is used almost exclusively for manufactured articles, the tonnage mined is of course very much larger than the weight of the articles manufactured and put on the market.

Uses.—Talc is employed in the arts in two distinct forms, as powder, or flour talc, and as pieces sawed into various sizes and shapes. The flour talc is now used as a base for fireproof paints, lubricants, and many of the cheaper soaps, for electric insulators, for boiler and steam pipe coverings, for foundry facings, for the dressing of skins and in the manufacture of dynamite, of the various toilet powders and of paper. Formerly certain varieties of clay were used as a filling in the manufacture of paper, but with the discovery of large deposits of talc, especially of the fibrous variety, in New York, talc has largely replaced them, its fibrous and pliable character giving additional strength as well as weight. The introduction of talc in the manufacture of toilet powders put on the market under the name of talcum powders gave a new use for the more valuable talc.

The soapstone, or steatite varieties of talc, are used for the most part in the manufacture of hearthstones, linings of furnaces, for cupola and converter linings in many steel works, for laboratory tables and ovens, for laundry tubs and slate pencils, and, to a limited extent, in building. It is also used quite extensively in the manufacture of soapstone griddles, foot warmers, boot driers, and for many other articles of everyday use.

TABLE 5.—DETAILED SUMMARY: 1902.

	United States.	New York.	North Carolina.	All other states.[1]
Number of mines or quarries	20	4	6	10
Number of operators	20	4	6	10

MAGNESITE

MAGNESITE.

By Joseph Struthers, Ph. D.

The output of magnesite in the United States is obtained solely from California. The mineral occurs in other states, but the deposits are not of sufficient extent or purity to render their exploitation a commercial possibility. The deposits of this mineral occur in several localities in California, but a mine located in Tulare county was the only one in active operation during 1902. It is impossible, therefore, without disclosing individual operations, to publish the complete statistics for this branch of the mining industry, and they are included in the group of "all other minerals" in the general tables. Of the magnesite mines which were idle during 1902, 2 are located in Alameda county, 2 in Napa county, and 1 each in Santa Clara, Sonoma, and Stanislaus counties, a total of 7. The mineral has also been found in San Bernardino county.

Production.—During 1902 the production of magnesite in California amounted to 3,086 short tons of crude ore. Of this product 2,236 short tons were calcined, the result being 1,050 short tons of the calcined product, valued at $15,780. The remaining 850 short tons of crude ore were valued at $3,859. The value of the entire product was therefore $19,639.

The quantity and value of crude magnesite marketed in the United States during the years 1891 to 1902, inclusive, including the value of the calcined product, is given in the following table from the report of the United States Geological Survey:

Table 1.—*Production of magnesite: 1891 to 1902.*

[United States Geological Survey, "Mineral Resources of the United States," 1902.]

Year.	Quantity (short tons).	Value.
1891	439	$4,390
1892	1,004	10,040
1893	704	7,040
1894	1,440	10,240
1895	2,220	17,000
1896	1,500	11,000
1897	1,143	13,671
1898	1,263	19,075
1899	1,280	18,480
1900	2,252	19,333
1901	13,172	43,057
1902	3,466	21,362

The census figures for 1902, as given in the text, are for the quantity mined that year, while those of the Survey include 380 tons, valued at $1,723, mined previously but sold in 1902.

The production of crude magnesite is practically under the control of one firm in California, which ships much of the output to two manufacturers of carbon dioxide gas for use in the production of the gas by calcination. The calcined product, essentially magnesium oxide, or magnesia, is returned to the shipper and is subsequently utilized by paper mills in California and Oregon. The demand for calcined magnesite for this purpose in the West is limited, and only a small portion of the available supply is utilized—a trade condition which is reflected by the different unit value of the calcined product from year to year when considered in connection with the quantities produced. Thus in 1900 the supply of calcined magnesite amounted to 1,013 short tons, and the average value per ton was $15.70; in 1901 the output, 4,726 short tons, far exceeded the demand, and the average value decreased to $5.57 per ton; in 1902 the quantity produced, 1,050 short tons, was again just sufficient to satisfy the normal consumption, and the average value per ton rose to $15.03.

Consumption.—It is impracticable to furnish accurate statistics of the consumption of magnesite and of magnesite products in the United States, owing to the fact that in the official reports no distinction is made between the imports of crude and of calcined magnesite; furthermore, the statistics of the quantity and value of imported magnesite bricks are not separately reported. During 1902 the imports of crude and calcined magnesite (which were chiefly from Greece and Austria) amounted to 49,786 short tons, valued at $373,928, as compared with 33,461 short tons in 1901. There was also a very large importation of magnesite bricks, but no statistics of their quantity or value are available. By adding the figures for imports to the figures for the marketed production, as given by the Geological Survey, an estimate may, however, be made of the consumption exclusive of the quantity contained in brick form; on this basis the

quantity of crude and calcined magnesite consumed in the United States during 1902 was 53,252 short tons, as compared with 46,633 short tons in 1901 and 31,076 short tons in 1900. These statistics show the increasing importance of magnesite in the industrial arts in the United States; they also show that only a very small fraction of the supply is of domestic origin.

The industry in the United States.—Magnesite is found in many localities in the United States—in California and in Massachusetts; at Bare Hill, near Baltimore, Md.; near Rye and at Stonypoint, N. Y.; near Hoboken, N. J.; in Yancey and Cabarrus counties, N. C.; in Chester and Lancaster counties, Pa.; in Arizona and in Texas. But the deposits have been worked with commercial success only in the first-named state. The deposits in California are quite widespread, occurring in the following counties: Alameda, Colusa, Fresno, Kern, Mariposa, Monterey, Napa, Placer, San Luis Obispo, Santa Clara, Stanislaus, Tulare, and Tuolumne. The only producing property during the year was in Tulare county, near Portersville, where the mineral occurs in a series of vertical and flat veins, in some cases 10 feet in width, and has wall rocks of serpentine and granite. Some of these veins outcrop boldly, and a few of them have been traced on the surface for several thousand feet. A large quantity of mineral has been disclosed by open cuts and a tunnel. A 10-ton kiln, using crude petroleum as fuel, serves to calcine the product, which is then shipped to paper mills, and a second kiln will be erected as soon as the demand warrants it. The calcining treatment, which is carried on at a temperature of 2,500° F., occupies from three to three and one-half hours; the carbon dioxide gas expelled is allowed to escape into the air. In the calcination of magnesite, 48 to 52 per cent of its weight is lost by the expulsion of the carbon dioxide. The cost of the calcined product at the kiln is from $12 to $14 per ton. The demand for magnesite has increased rapidly east of the Rocky mountains, but owing to the high cost of transportation from the Pacific coast, most of the mineral used is imported, mainly from Greece. An important problem of the industry in California is to reduce the cost of calcination to a point which will admit of the shipment of the calcined product to Pittsburg, where it might be used for the manufacture of magnesite brick and other refractory products, an industry in which at present magnesite imported from the island of Euboea, in Greece, and from Styria, in Austria, is used. Another important feature is the development of the iron and steel industry on the Pacific coast, which will give a strong impetus to the mining of magnesite and its manufacture into bricks and concrete for use as a basic lining of furnaces or converters, for treating phosphoric pig iron to make basic open-hearth or basic Bessemer steel.

The industry in foreign countries.—The greater portion of the world's production of magnesite at the present time comes from the deposits in Austria and Greece. During 1901 the exports of calcined magnesite from Austria amounted to 40,236 metric tons, valued at $321,800. The deposits in Austria have attained their greatest development near Vietsch. The formation is of the Silurian age and consists of argillaceous shales, quartzite, dolomite, and gneiss. The magnesite occurs in beds conformable with the strata and is usually seamed with calcite, dolomite, and quartz, with occasionally segregations of dolomite crystals; it is necessary, therefore, to cob and pick the mineral. The sorted ore, which usually contains from 90 to 96 per cent of magnesium carbonate, is calcined at a white heat in kilns lined with magnesite bricks at those sections where the temperature is the highest, in order to prevent the introduction of impurities into the material. The small amounts of silica and ferric oxide contained in the ore are sufficient only to sinter it. The kilns are continuous in action and yield 80 tons of calcined ore daily. This product is sorted mechanically for the removal of the fine dust, as well as quartz and other impurities, that may not have been separated in the preliminary cobbing process. The sorted calcined material is then crushed, formed into bricks in steel molds by hydraulic pressure of about 4,500 pounds per square inch, and finally burned in kilns at a high temperature, thus producing the solid and compact magnesite brick as it appears in the trade.

In Greece the magnesite mines are near Mantudi and Limni in the northern part of the island of Euboea. The mineral is in crypto-crystalline form and occurs in large veins in serpentine; picked samples contain as high as 98 per cent of magnesium carbonate, but the average composition approximates 95 per cent Formerly the sorted ore was calcined in kilns fired by wood, but this process has been cheapened by the introduction of modern shaft calciners using a local lignite for fuel. Ordinarily the completely calcined ore falls to powder when moved and causes the lower and cooler portion of the ordinary kiln to become choked with fine material, thereby preventing the access of air which is necessary for the combustion of the fuel. The modern furnace is constructed especially to overcome this defect. The magnesite from Euboea is exceptionally pure and on account of the absence of impurities, it sinters only at a very high temperature. As this magnesite is so highly refractory, it is necessary in the manufacture of bricks to add a suitable binding material. At the brickworks at Mantudi, a small proportion of serpentine is added to the mixture which is molded and burned at a temperature of 1,400° C. in a regenerative furnace of the Siemens type, yielding a very hard and dense brick.

Deposits of magnesite have been found at Sutton and Bolton, Ontario, Canada; near Frankenstein, Germany; in the Department of Ufa, southern Urals, Russia; in India; and at several localities in Hungary. A few of these deposits have been worked, but the output from them at the present time is very small, when compared with the total production of the world.

Occurrence and characteristics.—Magnesite, magnesium carbonate ($MgCO_3$), corresponds chemically to calcite, calcium carbonate ($CaCO_3$). In the pure state, it contains 47.6 per cent of magnesium oxide, and 52.4 per cent of carbon dioxide. When impure, magnesium silicate is present and at times iron oxide. Pure magnesite occurs in transparent, rhombohedral crystals; in the massive form it is compact and granular, resembling unglazed porcelain in appearance. In color it is generally white, but often of a yellowish, grayish, or even brownish tinge. The brownish color is imparted to the mineral by the impurity, iron oxide, which if present to the extent of several per cent forms the variety "breunnerite," or "brown spar," as it is sometimes called. In hardness magnesite varies from 3.5 to 4.5, and though brittle, it is exceedingly difficult to drill. Its specific gravity varies from 3 to 3.12.

The formation of magnesite, which is usually associated with serpentine, is attributed to the action of carbonated waters upon eruptive magnesium rocks, such as olivine (chrysolite); when this action has been carried nearer to completion, the serpentine also is decomposed, yielding as final products magnesite and quartz. While magnesite generally occurs associated with serpentine, it is found also with other magnesian minerals, as talc, brucite, dolomite, etc. It is sometimes found in gypsum, and when the veins are irregularly mixed, with the gypsum the mass forms the variety of marble known as "verd antique."

Uses.—In the crude condition magnesite is used largely for making carbon dioxide gas, either by the application of heat alone or by treatment with sulphuric acid. The carbon dioxide so produced is utilized largely either in the gaseous or liquefied state to "charge" or carbonate mineral waters and other beverages, and its use in mechanical refrigeration in warm countries and on shipboard is increasing. When crude magnesite is decomposed by sulphuric acid, magnesium sulphate is obtained as a by-product, which, being dissolved in water, filtered, and crystallized, yields Epsom salts ($MgSO_4$, $7H_2O$). During 1902 it is estimated that at least 17,500,000 pounds of this salt were produced in the United States. At least 90 per cent of the domestic output of Epsom salts produced during 1902 was consumed in the manufacture of dyes, laundry soaps, and paints, and in tanning leather; the remaining 10 per cent was used in the preparation of medicinal salts. Early in 1903 a combination was effected of the various concerns engaged in making Epsom salts in the United States. Crude magnesite is used to a minor extent in the manufacture of the magnesia alba of pharmacy. This preparation is a mixture of magnesium carbonate and hydrate.

The consumption of magnesite in its calcined state (which corresponds to magnesia, MgO) has increased very largely since 1899, owing to its uses in the form of bricks or concrete as a refractory lining for open-hearth furnaces and Bessemer converters in the steel industry, and for special parts of furnaces used in the smelting of copper and lead ores; as a lining for rotary kilns used in the manufacture of Portland cement; as a nonconducting covering for boilers, steam pipes, etc., to prevent loss of heat; and more recently in electric furnace construction as a refractory material. It is used also in the manufacture of paper stock by the sulphite process, the wood pulp being digested under pressure in calcium-magnesium acid sulphite, whereby the lignin which forms the coloring matter of the wood, as well as other incrusting material of the fiber, is converted into soluble products, which are subsequently removed by washing. The general adoption of the basic process of making steel has also largely increased the use of magnesite for furnace linings, especially in the form of bricks.

MINERAL INDUSTRIES OF PORTO RICO.

By William F. Willoughby.

The investigation of the mineral industries of Porto Rico for the year ending December 31, 1902, report of which is given in the pages that follow, representing, as it did, the first attempt to present a comprehensive exhibit of the character and importance of the mineral resources of the island and of their exploitation, had to contend with the difficulties usually attendant upon initial statistical or census work in any field. These difficulties consisted not so much in securing data concerning mineral deposits and their working, after their existence was known, as in securing information concerning such existence and working itself. In the present case this difficulty was especially acute owing to the lack of official data and the fact that in no case were mining operations being conducted as a regular industrial enterprise. Such work as was done during the year was almost wholly of a prospecting and experimental character. Even brickmaking and stone quarrying were carried on in an intermittent manner, bricks being made as demand arose for them and quarries being worked here and there by contractors in need of material for roadmaking.

In view of these conditions it was deemed that the most important work that could be done by the investigation would consist of presenting (1) such historical data as could be obtained regarding the search for, and discovery of, minerals in the past, and efforts that had been made for their utilization; (2) a statement of the laws in force regarding the location and exploitation of mining claims; (3) a list of all mineral deposits of which information could be secured by making the most thorough investigation possible; and (4) an account, with such statistical data as could be obtained, of work actually done during the year in the utilization or manipulation of such mineral resources.

In these efforts it is believed that, thanks to the cooperation of the different insular and local officials, a large measure of success has been attained. The thoroughness of the canvass may be seen from the following statement of the means employed in securing information. In addition to the personal researches of the author and his assistants, information was sought and secured from each of the sixty collectors and deputy collectors of taxes attached to the Treasury Department of the island, whose duties are such as to make them personally acquainted with every important taxpayer or industrial enterprise in their respective districts, from the twenty-odd internal revenue agents whose duties take them to every part of the island, no matter how difficult of access, and finally from all the contractors and superintendents engaged in the construction or maintenance of the highways. The commissioner of the district of Porto Rico and the chief of the Bureau of Mines under his jurisdiction likewise rendered every possible assistance in the way of furnishing data taken from official records and in directing all of their employees to furnish any information in their power.

Mining, as generally understood in the United States, has not up to the present time been a stable industry in Porto Rico. Certain minerals were known to exist by Ponce de Leon and his followers in the early part of the sixteenth century, but no systematic or scientific methods were then, or have been since, employed in their extraction. The absence of any relics pertaining to the period antedating the discovery of the island by the Spaniards would tend to show that metals were not used in the manufacture of warlike implements or domestic utensils, neither has there been unearthed any metal adornments, such as anklets, arm rings, or similar decorations with which primitive tribes conversant with the use of metals were wont to adorn their women folk. The complete absence also of shafts, tunnels, and other evidences of ore mining, such as are being constantly uncovered in other Spanish-American countries, would further tend to confirm the opinion that neither the Borinqueños nor their Spanish conquerors practiced mining except in a desultory manner, and the lack of historical mention of such industry likewise strengthens this belief. Fray Iñigo Abad, in his "History of Porto Rico" (1788), makes reference to early remittances of gold to the Spanish peninsula, but all the gold extracted was undoubtedly obtained from river washings by enforced native labor. In his description of the effects of the great hurricane of 1530 the same historian says: "Se volvian los ojos á las minas, las veian todas sumer-

gidas por las crecientes de los rios" (They turned their eyes to the mines, but found them all submerged by the overflow of the rivers).

Official or other reliable data relative to the geological formation of the island is also practically nonexistent. Some attempt to compile a report on the subject was made by Angel Vasconi, a Spanish engineer, and the result of his labors was laid before the directors of the Exposition of Mineralogy held at Madrid in 1883. The monograph comprising the report is not extant in Porto Rico, but a portion of the rough draft was found among the archives of the insular Bureau of Mines by its present chief and was largely drawn upon by the Governor of Porto Rico in his second annual report to the President of the United States. The information therein contained is considered worthy of reproduction as presenting in succinct and precise form what little is known of the mineral bearing formations which go to make up the soil and subsoil of this new possession of the United States.

[Extract from the second annual report of the Governor of Porto Rico to the President of the United States.]

Gold placers were worked for some years by the Spaniards in the first century of the conquest, and, according to official statistics, 2,700 pounds of gold were sent to Spain from the year 1509 to the year 1536. It is believed that that figure only represents the part belonging to the Crown of Spain—that is to say, the fifth of the total production during that period of time.

The Sierra de Luquillo, the more abrupt and the highest of all the mountains in Porto Rico, belongs to the main cordillera, or chain, which cuts the island from east to west, with a prolongation to the Windward Islands, by the east, and to the little island of Desecheo, situated opposite to Mayaguez and Añasco, by the west. That mountain, or sierra, is in the northeastern part of the island, and owing to its situation and the elevation of its hills—the highest being El Yunque, 1,200 meters [3,937 feet] above sea level—is the first vessels can distinguish in coming to Porto Rico. From El Yunque and the hills named Cuchilla Firme, Meseta, Peña Parada, and others, various rivers flow in which gold has been found. The Mameyes, one of the richer in gold, has as tributaries the rivulets known as Filipina, Cajones, Guaraguao, La Mina, La Máquina, Tabonuco, and Anon. In this last named, the Anon, some thirty-eight years ago, a rich concern did some work in the washing of sands or auriferous alluvia, obtaining from one to two pounds of fine gold per day. The rocks more abundantly found in the watershed of Mameyes River are eurite and porphyry, crossed with veins of quartz and iron pyrites. The alluvial lands occupy a good extension of the middle and lower parts of these watersheds, and are composed of clay, sand, and bowlders, forming deposits of analogous nature. Their depth is variable. In the valley of the Anon there are some cuts, from six to eight meters (20 to 26 feet) deep, made in such alluvial deposits with the view of exploiting the auriferous strata.

It is known that the watershed of the rivers Corozal, Negros, Congos, Cibuco, Mavilla, and Manatí contain auriferous sands. The idea which occurs to one examining the vicinity of Corozal is that that valley was emptied, through a process of erosion, by the diluvial waters, which produced in the calcareous soil cuts more than 130 meters [427 feet] deep, through which ran a stream. It is believed that the waters of that stream deposited the quaternary alluvia. The calcareous soil, said to be of the Tertiary formation, occupies the right shore of the river and extends itself by the north toward the sea. On the left shore, and in the bed of the river, the limestone has disappeared, giving place to potent strata of sandstone, on which the auriferous quaternary alluvia lay. The alluvial deposits are more potent the lower they are, and gold is found very near the surface in the higher and hilly parts, while, on the contrary, in the great deposits of the lower parts of the valley the auriferous strata are covered by sterile masses. Near the source of the Congos River, in the bed of it, and 25 centimeters (9.8 inches) deep, some pieces of quartz have been found containing from 8 to 10 grams [123 to 154 grains] of pure gold. In the jurisdiction of Corozal some washing machinery was established, and the result was from $2.17 to $4.30 for each ton of sand.

There are also, according to official information, some gold placers in Mayaguez, San German, Yauco, and Coamo. The gold is found in grains or nuggets of $2 or $3 value, and, rarely, nuggets of even higher value. In the Fajardo River a piece was found which weighed 4 ounces, and in the Congos another piece of 1 pound was also found; but the biggest piece of pure native gold was discovered in the lands belonging to Mr. Bou, in the jurisdiction of Corozal. That piece was sold to Mr. Bou by the finder for $200 in money and some other valuable things. In the bed of the Filipina rivulet there were obtained from 60 kilograms [132 pounds] of sand six-tenths of a gram [9 grains] of pure gold, which makes 10 grams [154 grains] for 1 ton of sand. The enterprises mentioned were abandoned, and the only work on the mines was done by the "lavadores," washmen. They use an instrument called "gaveta," made of wood, shaped like a plate, of 40 centimeters [16 inches] in diameter and 12 centimeters [5 inches] deep. In the watersheds of Mameyes River and in all the rivers crossing the jurisdiction of Corozal numbers of peasants can be seen engaged in the work of washing auriferous sand, from which they obtain gold in amount sufficient to pay for their support.

Since the American occupation, work on the mines has had renewed life, and the number of applications for mining concessions filed in the Bureau of Agriculture and Mines has increased. Up to July concessions have been granted for 107 hectares (264 acres) of land.

The minerals of copper obtained are: Ferriferous motley copper, native copper, green and blue carbonates, yellow copper sulphide, often accompanied with iron pyrites and iron oxides. Spanish explorers of the island paid little or no attention to copper. It is generally found along the main chain of mountains dividing the island from east to west, from the neighboring island of Vieques, and then following through Rio Blanco, Gurabo, Corozal, Ciales, Jayuya, Maricao, and some other places which belong to the southern chain of mountains, such as Las Piedras, Humacao, Ponce, Piñalejo, and also in the vicinity of the road from Caguas to San Juan, the richest place being the barrio of Rio Blanco, in the municipality of Naguabo. The first works for the exploitation of copper began in 1869. In the mine named "La Abundancia" some small excavations were made, and the superficial carbonate was gathered, and many tons of rich mineral were thus obtained. Like results were reached in the mines named Santa Amalia, La Castellana, and Santa Teresa, all located in the barrio of Rio Blanco. In the last-named mine copper indications were noted from the surface to a depth of 25 meters [82 feet], first as green carbonate with 23 per cent of copper, then as ferriferous motley copper, and, in some parts, yellow sulphide, very pure. In 1879, 10 tons of copper sulphide were obtained from the mine Santa Teresa, and 60 tons of carbonate of copper from the Santa Amalia. Owing to the difficulties and high prices of transportation, work ceased.

The existence of silver in the island has been officially recognized. On July 19, 1538, the "oficiales reales" wrote to the King of Spain that "veins of lead containing some silver have been found," and on March 29 of the following year they wrote, "With respect to the silver mines here discovered we arranged that that mineral be fused here, but there is no person who knows how to do it. In some places veins of that metal have been found, but nothing has been done, waiting the arrival of some one who knows how to fuse

and work it." In the History of Porto Rico, by Fray Iñigo Abad, with notes by Don José Julian Acosta, the statement is made that in the Serrania de Añasco there was a mine containing silver; and, in a report prepared in 1879 by the chief engineer of the bureau of mines, reference is made to certain samples of silver found in the barrio Llamos, of the municipality of Isabela. In other official documents the existence of silver in the northwestern part of the island is affirmed. Concessions have been made of silver mines in Naguabo, Corozal, Rio Grande, Fajardo, Lajas, and Las Piedras.

In the subsoil of the eastern part of the island there is feldspathic rock. This section is confined on the north by the Sierra de Luquillo, and on the south by the Pandura, parallel ranges of hills, and distant one from the other from 25 to 30 kilometers (16 to 19 miles). It is stated that the surface lodes occupy a large area, the depth not having been determined as yet. Iron is found, according to tests made, at the rate of 61 per cent of the mineral. Iron of excellent quality has been found in the barrios Mameyes and Jayuya, municipality of Utuado, and in Luquillo, Piedras, Naguabo, Humacao, Gurabo, Patillas, San Lorenzo, and Arroyo. The concessions of iron mines are numerous. Some efforts are being made now with the view of organizing enterprises for the exploitation of iron in the eastern part of the island.

There are in the island, according to official information, some deposits of lead minerals. Good samples of galena have been found in Arroyo, Mayaguez, and Naranjito. There are two concessions granted in the municipality of Guayama, one being for the exploitation of lead and the other for argentiferous galena. Minerals containing some amount of peroxide of manganese have been gathered in the vicinity of Corozal. Native bismuth has been discovered in Ponce. Samples of platinum, tin, and mercury have been obtained in the jurisdiction of Corozal.

All other official reports touch but lightly on the mineral resources of the island and do not convey any information not embodied in the foregoing extract. Mr. Robert T. Hill, of the United States Geological Survey, in his accurate and interesting work entitled "Cuba and Porto Rico," devotes but ten lines to the subject, saying:

A little placer gold is found in the rivers of the Sierra Luquillo and Corozal, and mercury in the Rio Grande. Gold was formerly mined by the early Spanish settlers and is still taken out in small quantities by the natives. Molybdena, magnetic pyrite, manganite, limonite, chrysocolla, epidote, and garnet are the minor minerals found. Specular iron is reported in several places, notably in the river Cuyul. Magnetic iron is also reported from Gurabo and Ciales. Crystals of quartz are found in the Rio Prieto, agate of good quality at Caja de Muertos, and malachite at Rio Blanco.

MINING LAWS.

Notwithstanding the absence of anything approaching an organized mining industry in Porto Rico there is, nevertheless, a complete system of laws and regulations governing the right to exploit both precious and base metals in the island.

This is substantially contained in the law of July 6, 1859, and the ministerial order of December 29, 1868, enacted originally for application in the Spanish peninsula only, but subsequently extended to Porto Rico by the law of May 3, 1895. Many of the provisions of these statutes have by reason of the change of sovereignty become inapplicable, and it is understood that a new mining law is being drafted and will be presented at the next session of the insular legislature. In so far as possible, however, the principles and procedure of the existing laws are being observed, and deficiencies arising from changed political conditions treated by analogy.

Minerals subject to mining claims are divided by the law into three classes, as follows:

Class I: Minerals of an earthy nature, minerals of a siliceous nature, slates, minerals of a sandy nature, granites, basalts, limestones, gypsums, sands, marls, clayey earths, construction materials in quarry formation.

Class II: Placers, metallic sands or alluvia, bogs, emery, ochers and almagras, scoria and mineral tailings, peats, pyritic earths, aluminous earths, magnesium earths, salt deposits, lime phosphates, barytes, fluorspars, steatites, ravolins, clays.

Class III: Metallic veins, anthracites, pit coals, lignites, asphalts, bitumens, petroleum and mineral oils, graphites, saline substances, including alkaline and terraceous salts, either solid or in solution, copperas, sulphur, precious stones, iron ores.

In order to obtain legal title to a mining claim the claimant must submit a petition to the Commissioner of the Interior of Porto Rico setting forth the area of the desired claim, the class of mineral to be worked, and the name of the owner of the property wherein the claim is situated. He must also furnish a survey of the claim and, within ten days from date of filing his petition, must deposit the sum of $36 if the claim does not exceed in area 12 pertenencias (30 acres), and $1.20 for each additional pertenencia. No claim can be filed for less than 4 pertenencias, but there is no limit to the number of pertenencias that may be included in one claim. Each pertenencia must, however, be contiguous along the whole of one of its sides to some other pertenencia of the same claim, and must consist of a regular square, each side measuring 100 meters (328 feet). The aforesaid deposit is to cover the expense of an official survey made later by the Government. The first conditions being complied with, the petition is advertised for sixty days to enable protests to be filed, which protests are submitted to the claimant for reply within twenty days. The complete brief is then passed upon by the Commissioner of the Interior of Porto Rico, and his decision, if favorable to the claimant, is followed by the appointment of a surveyor to lay out the claim and the payment of a further fee by the claimant, amounting to 60 cents per pertenencia ($2\frac{1}{2}$ acres), to cover expenses of title. A title signed by the Governor is then issued, and is valid forever, subject to an annual rental (canon de minas) of $2.40 per pertenencia for precious metals, or 96 cents per pertenencia for base metals. This title does not carry any obligation to work the mine, and lapses only on failure to pay the annual rental.

Pending legislation relative to the disposition of public lands (terrenos baldios), no mining claims are being allowed on public property.

PRECIOUS METALS.

There are at present twenty mining claims registered on the books of the Bureau of Mines, none of which, however, is in operation.

Registered mining claims of precious metals.

NAME OF OWNER.	Name of mine.	LOCATION OF MINE.			AREA OF MINE—		Class of mineral said to exist.

D. McLean	Vanderbilt	Bayamon	Corozal	Dos Bocas	12	30	Silver and other.
Hogan & Pierce	Reina del Cobre	do	do	do	12	30	Do.

All of these claims have been filed since the American occupation of the island, and some little exploration work has been done in the case of a few of the claims situated in the Corozal district. The owners of each of the above-enumerated claims have been interrogated by letter as to whether their respective claims were in operation, but except from the owners of two of these claims (Augusta and La Palma) no response has been elicited. The owners of the other mines are not to be found at present in the island. It may, therefore, truthfully be said that ore mining of precious metals is entirely prospective and confined to the filing and registration of the above-mentioned claims, none of which is being exploited.

PLACER GOLD MINING.

Such gold mining as is actually engaged in at present in Porto Rico is entirely of the placer type, unimportant in scope and confined to the Corozal district of the island. There are some twenty or more miners of the peon class engaged steadily in the work of extracting gold from the sands of the river by means of an oscillating movement of the hands applied to a wooden disk in which the sands are washed. From the best information obtainable, the value of the gold thus secured daily will aggregate, approximately, $25. It is understood that Mr. Henry D. Sayre, who is the *concessionaire* of eleven mining claims in the Corozal district, intends shortly to operate on an extensive scale. Mr. Sayre is an experienced miner, who has invested a considerable sum of money in exploration, surveys, and assays in Porto Rico, and is said to be very favorably impressed with the mineral wealth of the Corozal district. He has recently applied to the executive council of Porto Rico for a franchise authorizing him to divert the waters of the Mabille river from their natural course with a view to obtaining the deposits of gold in the river bed. Whether any attempt at ore mining will be made by Mr. Sayre is not at present known, but it is understood that he claims to have discovered the original veins from which the deposits in the river bed are derived. Although there is evidence of placer mining having been practiced in other parts of the island as well as in the Corozal district, particularly in the vicinity of San German, no mining for gold is at present carried on outside of the Corozal region. This failure to operate elsewhere in the island is doubtless due to the belief that the gold deposits in other sections have become so nearly exhausted as to preclude their extraction in quantities profitable even for the peon class.

BASE METALS.

The foregoing description of the situation relative to precious metals applies almost in its entirety to the baser metals. The following mining claims have been filed and are registered in the office of the Commissioner of the Interior of Porto Rico, but no single one of the mines appearing in the list is actually being operated.

Registered mining claims of base metals.

A letter of inquiry was sent to each of the owners of the above claims. The replies received may be classified as follows:

Not operated.—Pilar, Natividad, Aurora, Fortuna, Merceditas, Soledad, Eugenia, Capron, Santa Agueda, Eloisa, Esperanza, Carranzana, San Miguel, San Anton, Begoña, Luisa, Buen Suceso, Providencia, Sabina, Caridad, La Fe, San Ramon, San Jose, Asuncion, Valentina, San Pedro, Palonia, Santo Tomas, Mercedes.

Operations suspended.—Estrella, Rosita.

Operations confined to exploration and assay.—Maria Josefina, Celina.

Not reported.—Corcega, Freddie, Anaconda No. 2, Perseverancia, Santa Amalia, Idalia, El Bronce, La Victoria, Maria, Casualidad, Seguridad, Palmira, Margarita.

It is understood that some of the iron ore deposits are of an exceptionally rich character, fully equal in percentage of mineral to the famous Daiquiri mines near Santiago de Cuba. These deposits are situated inland some five or six miles from the eastern seacoast town of Naguabo, and can not be operated with profit until means of transportation is furnished to tide water.

SALT.

The production of salt in Porto Rico is confined exclusively to the southern coast. The process of solar evaporation is the only one employed, and that in its most primitive form. The consumption of this article, estimated from the best data obtainable, is about 300,000 quintals (15,000 tons) per year. All salt required for home consumption, as well as a large amount in excess for export purposes, could readily be produced in the island, but owing to insufficient capital (as alleged by persons engaged in the industry), want of skill in operating, or inclemency of the elements, and notwithstanding the fact that a protective duty of 12 cents per hundredweight has been imposed on foreign salt introduced into Porto Rico, thousands of tons of this commodity are annually imported from Curaçao. The Curaçao salt meets with ready sale here at prices ranging from 20 to 50 cents per quintal, whereas it is claimed that with proper management salt can be pro-

duced in Porto Rico at a maximum cost of 10 cents per quintal.

The production of salt in 1902 was almost nil. A canvass gave the following results:

Production of salt: 1902.

NAME OF OPERATOR.	Address of operator.	LOCATION OF WORKS.		Salt produced.	Package.	Value of package.	Net value of salt.	Process employed.
		Department.	Municipal district.					
Juan Padilla	Cabo Rojo	Ponce	Yauco	[1]5,000	Sack	$0.03	$1,250	Solar.
Anecto Caballero	Salinas	Guayama	Salinas	[1]2,000	do		800	Do.
Juan Miguel Toro	Cabo Rojo	Mayaguez	Cabo Rojo	[2]650	do		540	Do.
U. Lopez & Co	San German	do	Lajas		do	.03		Do.

[1] Hundredweight. [2] Bushels.

In view of the abnormally small production of salt in Porto Rico in 1902, shown in the above statement, it is of interest to reproduce here the reasons advanced therefor by some of the operators:

The reason of the production of the extremely small quantity of 650 bushels is the heavy rains which fell during the year 1902. In other years six, eight, or ten times the amount was produced.

The insignificant duties paid by foreign salts give rise to the anomalous condition in Porto Rico of importations from Curaçao and other places of a larger amount of salt than is manufactured in the island.

During the year 1902 no salt was produced from the deposit (Fortuna), the hurricane of 1899 having completely destroyed its utility to its former owners, and the whole of said year (1902) being employed by its present lessees in getting it into shape again.

Said deposits (Carmen and Monserrate) have in former years produced 25,000 to 30,000 quintals. The small production in 1902 was owing to the early rains along this coast.

The salt industry of Porto Rico does not produce the fifth of what it should, owing to the lack of capital on the part of the operators. With an initial expenditure of $5,000 the deposit I own should produce 100,000 quintals of salt.

CLAY PRODUCTS.

No attempt has heretofore been made in Porto Rico to canvass this industry, consequently there were no initial data available to aid in the present study. It was known, in a general way, that bricks were made in the island, also that no modern machinery was utilized in their manufacture.

That the industry was not extensive or important was quite evident from the absence of brick edifices and the almost universal use of lumber in the construction of dwelling houses, except in the cities of San Juan, Ponce, and Mayaguez. This first inquiry, therefore, could not be other than crude and incomplete, by reason of the following facts: (1) No previous statistics existed showing establishments engaged in the industry; (2) brickmaking was not engaged in continuously by any one establishment, ovens being baked, from time to time, as the necessity demanded; (3) lack of precise information on the part of the operators themselves as to number of bricks made, their actual cost, average selling price, etc. For the foregoing reasons it is apparent that many persons who engage in the manufacture of brick as occasion therefor arises could not be reached at all. In the brief period at the disposal of the writer it was not possible to ascertain the location of more than 35 operators. Of these, 30 were successfully interrogated, with the results shown in the following table:

Clay products: 1902.

NAME OF OWNER.	LOCATION OF OFFICE AND FACTORY.		COMMON BRICK.			KILNS.

Total			3,837,255	25,899			45

PORTO RICO—OX-POWER WHEEL FOR MIXING CLAY.

PORTO RICO—MOLDING BRICKS BY HAND.

The foregoing table shows that in 45 kilns 3,837,255 common bricks, valued at $25,899, were produced in 1902, or an average price of $6.75 per thousand. It is not believed, however, that this actually represents the total number of bricks manufactured in one year in Porto Rico; probably three times the above number would more nearly approach a correct estimate. The process employed is absolutely and literally the hand process, and consists in mixing the clay with water in a wooden trough until the requisite consistency is obtained. The mass is then molded into bricks by hand, the operator employing a wooden mold for that purpose. The crude bricks are afterwards placed in a brick oven and baked, when they are ready for market. Bricks made in this manner are not nearly so durable as those manufactured in the United States by means of approved modern machinery. Clay roofing tiles were extensively manufactured in Porto Rico at one time, but since the introduction of cheap iron roofing have entirely disappeared from use.

LIMESTONE.

With the exception of the fringe of flat lands lying between the coast line and the mountainous formations in the interior, the island of Porto Rico is practically one vast limestone deposit. Owing to its abundance and accessibility, and to the fact that its conversion into the proper form for use in building and kindred purposes requires no large outlay of capital, the industries having to do with lime rock, while quite numerous, are too scattered and unimportant to admit of the compilation of statistics on any elaborate scale. It is by reason of the foregoing considerations, also, that limestone and its products command no stable price in Porto Rico. Owing to the propinquity of certain quarries to points at which the material is needed, owners of such quarries can at times find a market for limited quantities of the stone at prices ranging from 3 to 10 cents per cubic meter. In such cases, however, the actual work of the extraction of the stone and its subsequent delivery to the place where required is generally attended to by the purchaser of the stone rather than by the owner of the quarry, and on account of the insignificant value of the material no attempt is made to keep an accurate record of the quantity used. By far the most important item of expense in connection with the use of the stone is that of transportation. The following table of quarries adjacent to the principal public highways already constructed or in course of construction in Porto Rico, many of which are themselves constructed of and upon limestone formations, will serve to illustrate the bountifulness of the supply of lime rock in the island. A list is given of the quarries that have been opened up and from which limestone has been actually extracted. These quarries are grouped according to the highway near which they are located, and their exact location is shown in the first column, which gives the number of kilometers and meters with the equivalent in miles and yards they are distant from the town first mentioned after name of the road at the head of the respective groupings:

Road from San Juan to Ponce.

The statements in regard to limestone preceding the above table apply with equal force to lime in its commercial forms. Practically every farmer in the interior of the island can, and does, produce lime in greater or less quantities, according to his needs, of which no account is kept. A canvass of such persons as could be ascertained to be engaged in the sale of lime in any of its forms gave the results appearing in the following table:

Production of limestone: 1902.

NAME OF OWNER.	LOCATION OF QUARRY.		LIMESTONE QUARRIED.						CRUSHED STONE FOR ROADMAKING.			Total value.	Condition of trade in 1901 compared with 1902.
			For building purposes.			Stone burned into lime.			Quantity—		Value.

[1] For railroad ballast.
[2] Includes 15 cubic meters (20 cubic yards), valued at $45, used for flagging.
[3] Includes 4,500 cubic meters (5,886 cubic yards), valued at $4,500, used for railroad ballast.

Whenever the demand is such as to make the production of an oven of lime sufficiently lucrative the farmer will prepare one and take it to the nearest market. The production of lime in Porto Rico, therefore, is important rather by reason of the large number of persons engaged therein on a small scale than on account of commercial importance. A certain amount of lime is used by the sugar factories to clarify sirup. In response to interrogatories as to quantity and cost of the lime thus used at the more important factories in the course of a year, the owners stated that where the lime was not to be had on their own premises it was usually obtained from some neighboring deposit gratis.

The limestone formations may be divided into two classes, white and yellow. There are also deposits, few in number, of a blue limestone, somewhat resembling granite formation, and of much harder composition than either the white or yellow varieties mentioned above.

PHOSPHATE ROCK.

There are four phosphate rock mining claims registered in the office of the Commissioner of the Interior of Porto Rico, none of which is being operated at present, viz:

Registered mining claims of phosphate rock.

NAME OF OWNER.	Name of mine.	LOCATION OF MINE.			AREA OF MINE—		Class of mineral.
		Department.	Municipal district.	Ward.	In hectares.	In acres.	
Alfredo Collado	Fortuna	Mayaguez	Cabo Rojo	Monte Grande	6	15	Phosphate rock.
Miguel Arzuaga	La Confianza	Arecibo	Manati	Las Boquillas	6	15	Do.
Joaquin de Alarcon	Trabajo	Aguadilla	Isabela	Arenales Bajos	12	30	Do.
J. Sanchez Valdes	Joachin and San Jose.	Ponce	Ponce		12	30	Do.

There are other deposits of phosphate rock not registered, as shown in the following table, one of which it is claimed produced 50 tons during the year 1902:

Unregistered mining claims of phosphate rock.

NAME OF OWNER.	Address of owner.	LOCATION OF MINE.			TOTAL AMOUNT IN TONS.		Value of sales.
		Department.	Municipal district.	Ward.	Produced.	Sold.	
Domingo Emanuelli	Coamo	Ponce	Coamo	Palmarejo	50	35	$105
M. Porrata Doria	Ponce	do	Ponce	Caja de Muertos			
Fausta Aponte	Coamo	do	Coamo	San Ildefonso			
Miguel Arzuaga	Barceloneta	Arecibo	Manatí	Las Boquillas			
José Sanchez Valdes	Ponce	Ponce	Ponce	Machuelo			
Felipe Alfaro	Isabela	Aguadilla	Isabela	Arenales Bajos			

The insular government is the owner of the largest known deposit of phosphate rock, which is situated in the island of Caja de Muertos. This deposit was formerly operated on an extensive scale and the product shipped to Germany. It is idle at the present time, however, pending action by the executive council of Porto Rico upon a franchise to work the deposit, for which application has been made. In statistics previously compiled on this subject, deposits of bat guano have been confused with phosphate rock in consequence of such guano being found upon rocks or in caves of a phosphatic character.

GRANITE.

It is not believed that any real granite is to be found in Porto Rico. Two residents of the central section of the island claiming to have discovered granite on their premises gave the information that only 18 cubic meters (24 cubic yards) had been sold in the rough for curbing purposes and 81 cubic meters (106 cubic yards) crushed for roadmaking purposes. It is probable, however, that the stone in question is of dioritic formation and not granite, as they allege.

MINERAL SPRINGS.

There are four widely known mineral springs in Porto Rico, the waters of which contain medicinal properties of no mean value. They are:

Mineral springs in Porto Rico.

NAME OF OWNER.	Residence of owner.	Date of report.	Name of spring.	LOCATION OF SPRING.			Remarks.
				Department.	Municipal district.	Ward.	
Sucesión Usera	Coamo	June 4, 1903	Coamo, Maria	Ponce	Coamo	San Ildefonso.	Used only as baths.
Virella U. Hermanos	Arroyo	do	Carmen, Dolores	Guayama	Arroyo	Algarrobo	Do.
Guillermo Orrach	Caguas	do	Florencio	do	Caguas	Bairoa	Do.
Sucesión Ortiz	Ponce	May 22, 1903	Quintana	Ponce	Ponce	Portugues	Do.

The first-named spring is famous locally as a health resort, there being a well-appointed hotel furnishing accommodations for 110 guests. The waters are supplied to visitors in the form of hot and cold baths and for drinking purposes, but have never been bottled, nor has any attempt been made to put them on the market. The springs run from a soft red sandstone, at an altitude of 196.85 feet above sea level, with a temperature, at point of exit, of 43° C. An analysis by Quintanilla in 1891 gave:

Gases in solution, per liter of water at 0° C. temperature and 760 millimeters pressure:

	Cubic centimeters.	Cubic inches.
Nitrogen	13.740	0.84
Oxygen	1.761	0.11
Hydrogen sulphide	1.967	0.12

Fixed elements, per liter:

	Grams.	Grains.
Free carbonic acid	0.01296	0.20000
Sulphate of lime	0.79903	12.33063
Sulphate of soda	0.52531	8.10658
Chloride of potash	0.00031	0.00478
Chloride of sodium	0.22054	3.40337
Silicate of soda	0.08127	1.25416
Carbonate of soda	0.03503	0.54058
Ferrous carbonate	0.01114	0.17191

Traces of tannic, nitric, and boric acids and bromine and lithia.

The Florencio springs are not operated for the benefit of the public. There is a private bath house used by the family of the proprietor and by other persons by special permission. The waters have never been bottled nor put on the market. The proprietor states that local physicians prescribe the waters for skin diseases and stomach troubles, but that a scientific analysis has never been made.

PORTO RICO—LIMESTONE QUARRIES.

The Quintana springs, near the town of Ponce, are also quite extensively known locally as possessing excellent medicinal virtues. The waters are administered in the form of baths, but within recent months, owing to the bad state of the road leading to the baths and the abandoned condition of the establishment itself, the springs have ceased to be a public resort. An analysis made in San Juan in 1894 classifies the water as colorless, odorless, transparent, salty, and somewhat bitter in taste; no matter in suspension; density, 1.0057.

Gases in solution:	Cubic centimeters.	Cubic inches.
Ozone	0.0191	0.0012
Oxygen	0.0100	0.0006
Carbonic acid	0.0025	0.0002
Fixed elements, per liter:	**Grams.**	**Grains.**
Chloride of sodium	0.519	8.009
Chloride of magnesia	0.015	0.231
Sulphate of soda	0.123	1.898
Sulphate of potash	0.021	0.324
Sulphate of lime	0.081	1.250
Carbonate of lime	0.122	1.883
Ferrous carbonate	0.012	0.185
Silica	0.032	0.494
Organic matter	0.050	0.772

Traces of manganese and bromine.

The Arroyo springs are not operated by the proprietors, who state that no trustworthy analysis of the waters has as yet been made.

Accompanying this report is a map showing approximately the location of mining claims, salt deposits, and mineral springs in Porto Rico. Owing to the fact that no scientific triangulation or survey of the island has ever been made, it has been impossible to indicate on the map with exactness the geographical position of these claims. It is believed, however, that the general purpose of showing the approximate location of the mining deposits of Porto Rico is sufficiently well served. The reason given above with respect to the want of exactness in the location of mining claims applies to the boundaries separating municipalities as well.

Every effort was made to obtain data showing the number of persons employed during the year in the exploitation of the mineral resources of the island. For obvious reasons such an effort could not meet with any great degree of success. As has been stated, in no case were mines or quarries operated during the year as a continuous industrial enterprise. Even in respect to such work as brickmaking, lime burning, or quarrying, operations were of an intermittent character. As regards quarrying, the rock was usually taken out by the contractors engaged upon road construction or repair in connection with their other work. No amount of research, therefore, would have permitted a definite statement either of the total output or of the number of persons employed. The best that can be done is to make a rough estimate, based upon the general information secured, in obtaining the data for the report of the probable average number of persons that may be said to have gained a livelihood in some capacity in connection with the exploitation of the mineral resources of the island.

In respect to the extraction of precious metals, a fair estimate would put the average number of men constantly employed during the year in exploitation work for gold mines and the laying out of claims and similar work at twenty-five. Thirty additional men were probably employed in placer mining, chiefly in the Corozal district. Exploitation and field work in connection with copper mines probably did not engage more than ten men. About one hundred and fifty men may be said to have been constantly employed in the operation of salt mines. Brickmaking probably gave employment to an equivalent of two hundred men working all the year. Estimating from the amount of limestone extracted for the purpose of roadmaking and repairs and for burning, an exceedingly rough approximation would place the amount of labor expended in limestone quarrying operations at five hundred men. As only 50 tons of phosphate rock were mined during 1902, probably not more than two or three men had constant employment during the year.

That Porto Rico possesses mineral resources that will be of great value to the island in future years there can be no doubt. In their utilization the stage as yet has only been reached where efforts are being made to determine more exactly their character and extent. Authorization for water rights and concessions of various characters are being constantly sought of the insular government, and it is certain that when another investigation along the lines of the present one is made the phase of industrial exploitation in respect to a number of minerals will have been definitely entered upon.

APPENDICES

Appendix A.—SCHEDULES
Appendix B.—INSTRUCTIONS TO SPECIAL AGENTS
Appendix C.—INSTRUCTIONS FOR EDITING AND REVISING THE SCHEDULES

APPENDIX A.

SCHEDULES.

Schedule No. 6.—Intended for all mineral industries for which no special schedule is provided. (*Number printed, 100,000.*)

UNITED STATES CENSUS OFFICE.
Special Schedule No. 6.

DIVISION OF MANUFACTURES.
S. N. D. NORTH, Chief Statistician.

MINES AND QUARRIES.

Name of mine or quarry .....
Character of mineral .....
Name of company, firm, or individual owner .....
Location of mine or quarry: State .....; County .....
Nearest city or town .....; Post office .....
General office at .....
.....

UNITED STATES CENSUS OFFICE,
Washington, D. C., January 2, 1903.

By section 7 of the act of Congress for the establishment of a permanent Census Office, approved March 6, 1902, the Director of the Census is required to prepare a report on mines, mining, quarries, and minerals and the production and value thereof, including gold in divisions of placer and vein, and silver mines, of the United States, and the following schedule has been formulated for that purpose.

For the convenience of producers, the United States Geological Survey will distribute and receive these schedules in connection with the returns for its annual report.

The information returned on this schedule should cover the business year of the establishment most nearly conforming to the year ending December 31, 1902.

All answers will be held absolutely confidential. No publication will be made in the census reports disclosing the names or operations of individual establishments in any particular. Special agents and enumerators of the census are liable to a penalty of $500 if they disclose any information obtained in their official capacity.

WILLIAM R. MERRIAM,
Director of the Census.

Extract from act of Congress, March 3, 1899:

SECTION 22. * * * "And every president, treasurer, secretary, director, agent, or other officer of every corporation, and every establishment of productive industry, whether conducted as a corporate body, limited liability company, or by private individuals, from which answers to any of the schedules, inquiries, or statistical interrogatories provided for by this act are herein required, who shall, if thereto requested by the Director, supervisor, enumerator, or special agent, willfully neglect or refuse to give true and complete answers to any inquiries authorized by this act, or shall willfully give false information, shall be guilty of a misdemeanor, and upon conviction thereof shall be fined not exceeding ten thousand dollars, to which may be added imprisonment for a period not exceeding one year."

CERTIFICATE.

This is to certify that the information contained in this schedule is complete and correct to the best of my knowledge and belief.

.....
(Signature and official designation of the person furnishing the information.)

.....
(Signature of special agent.)

1. Character of present organization, whether individual, firm, limited partnership, cooperative association, or incorporated company: .....
2. Capital stock, bonds, dividends, and assessments (if an incorporated company):

	BONDS.		PREFERRED STOCK.		COMMON STOCK.	
	Number.	Total par value.	Number of shares.	Total par value.	Number of shares.	Total par value.
Authorized	.....	$.....	.....	$.....	.....	$.....
Issued to the end of the year	.....	.....	.....	.....	.....	.....

Dividends and interest, if any, paid during the year:

Common stock, rate .....; amount, $.....

Preferred stock, rate .....; amount, $.....

Bonds, rate .....; amount, $.....

Assessments: Total amount levied, if any, since organization of company ..... $.....

3. Persons employed:

CLASSES.	Average number employed during the year.	Total amount paid in wages or salaries during the year.
Above ground:		
General officers	.....	$.....
Superintendents, managers, foremen, surveyors, etc	.....	.....
Clerks	.....	.....
Engineers, firemen, machinists, blacksmiths, carpenters, and other mechanics	.....	.....
Miners or quarrymen and stonecutters	.....	.....
Boys under 16 years	.....	.....
All other employees	.....	.....
Below ground (not for quarries or surface mines):		
Foremen	.....	.....
Miners	.....	.....
Miners' helpers	.....	.....
Boys under 16 years	.....	.....
All other employees	.....	.....
Total	.....	.....

(Account for all persons employed at the mine or quarry. Give the total salaries and wages paid, which should include board or rent furnished as part compensation. The wages reported for miners or quarrymen and stonecutters should be their net wages, and should not include the cost of supplies furnished by the company and charged to them, such as explosives, lamp oil, etc., and

blacksmithing charges. Care should be taken that those employed "above ground" and those "below ground" be reported separately. Stockholders of corporations are not to be reported unless they are salaried officials. Amounts paid for contract work, not done by employees hired directly, and the number employed in such work, must not be included in this inquiry, but be reported in answer to Inquiry 6. The average number employed during the year is the number that would be required, at continuous employment for the twelve months, to produce the quantity of product reported.)

AVERAGE NUMBER OF WAGE-EARNERS AT SPECIFIED DAILY RATES OF PAY.

OCCUPATIONS.	Less than $0.50.	$0.50 to $0.74.	$0.75 to $0.99.	$1.00 to $1.24.	$1.25 to $1.49.	$1.50 to $1.74.	$1.75 to $1.99.	$2.00 to $2.24.	$2.25 to $2.49.	$2.50 to $2.74.	$2.75 to $2.99.	$3.00 to $3.24.	$3.25 to $3.49.	$3.50 to $3.74.	$3.75 to $3.99.	$4.00 to $4.24.	$4.25 and over.
Engineers																	
Firemen																	
Machinists, blacksmiths, carpenters, and other mechanics																	
Miners or quarrymen and stonecutters																	
Miners' helpers																	
Timbermen and track layers																	
Boys under 16 years																	
All other employees, not including those on salaries																	

AVERAGE NUMBER OF WAGE-EARNERS EMPLOYED DURING EACH MONTH.

MONTH.	Men 16 years and over.	Boys under 16 years.	MONTH.	Men 16 years and over.	Boys under 16 years.
January			July		
February			August		
March			September		
April			October		
May			November		
June			December		

(Only wage-earners should be reported, including miners working on tonnage and other pieceworkers. Do not include firm members, general officers, superintendents, managers, foremen, clerks, and other salaried employees.)

4. If mining or quarrying is paid for by ton, car, yard, or other unit, give rate paid and character of unit, ...

Average number of employees engaged in this class of mining, ...

Total amount paid for such work, $.....

(The rate paid for mining or quarrying not done by the day should be reported, and the average number of employees engaged in such work and the total amount paid.)

5. Time in operation:

Total number of days in operation during the year, ... Number of hours in operation per day, ... Number of shifts of workmen, ... Number of hours to shift, ...

6. Contract work:

Amount paid, if any, for tunneling, shaft sinking, boring test holes, etc., if not done by employees hired directly by this establishment, $.....

Average number of men employed on such work, ...

Number of days employed, ...

7. Supplies and materials:

Total cost of supplies and materials of all kinds used during the year, including freight paid on the same, $.....

(The actual cost of all supplies and materials used during the year, including freight paid on the same, must be reported. The cost of the following materials should be reported under this inquiry: Lumber and timber used for repairs, mine supports, track ties, cars, and all other purposes; iron and steel for blacksmithing, rails, frogs, sleepers, etc., for tracks and repairs, parts of machinery and tools used for renewals and repairs; explosives, water for boilers and for other purposes, fuel, illuminating and lubricating oils, machinery supplies, etc.)

8. Miscellaneous expenses:

ITEMS.	Amount.
Royalties and rent of mine and mining plant	$.....
Amount paid for rent of offices, taxes, insurance, interest, advertising, office supplies, law expenses, injuries and damages, telegraph and telephone service, gas, and all other sundries not reported elsewhere	.....
Total	$.....

(All items of expense incident to the operation of the mine or quarry, not accounted for under Inquiries 3 and 7, must be reported here. Do not include any portion of the freight reported under Inquiry 7 as paid on supplies and materials.)

9. Product:

Total quantity of mineral or stone mined during the year, ...

Total value at mine or quarry, $.....

(Under this inquiry should be reported the quantity and value of all mineral or stone mined during the year, f. o. b. at mine or quarry, as reported to the United States Geological Survey.)

10. Power:

a. Power owned—

CLASS.	Number.	Total horsepower.
Engines: Steam		
Gas and gasoline		
Water wheels		
Electric motors		
Other power (specify kind)		

b. Power *supplied to* other establishments, if any—horsepower, ...

c. Power *supplied by* other establishments, if any—kind of power, ...; horsepower, ...; name and address of establishment supplying same, ...

(Under this inquiry should be reported all mechanical power employed, either owned or rented, including the number and horsepower of all engines, motors, water wheels, etc., used for hoisting, derricks, surface machinery, ventilating, pumping, and all other purposes.)

Special Schedule No. 8.—For coal mines. (*Number printed, 35,000.*)

First page same as Schedule No. 6.

Inquiries 1 and 2 same as Schedule No. 6.

3. Persons employed:

CLASSES.	Average number employed during the year.	Total amount paid in wages or salaries during the year.
Above ground:		
General officers		$.....
Superintendents, managers, foremen, surveyors, etc		
Clerks		
Engineers, firemen, machinists, blacksmiths, carpenters, and other mechanics		
Boys under 16 years		
All other employees		
Below ground:		
Foremen		
Miners		
Miners' helpers		
Boys under 16 years		
All other employees		
Total		

(Account for all persons employed at the mine. Give the total salaries and wages paid, which should include board or rent furnished as part compensation. The wages reported for miners should be their net wages, and should not include the cost of supplies furnished by the company and charged to them, such as explosives, lamp oil, etc., and blacksmithing charges. Care should be taken that those employed "above ground" and those "below ground" be reported separately. Stockholders of corporations are not to be reported unless they are

salaried officials. Amounts paid for contract work, not done by employees hired directly, and the number employed in such work, must not be included in this inquiry, but be reported in answer to Inquiry 6. The average number employed during the year is the number that would be required, at continuous employment for the twelve months, to produce the quantity of product reported.)

AVERAGE NUMBER OF WAGE-EARNERS AT SPECIFIED DAILY RATES OF PAY.

OCCUPATIONS.	Less than $0.50.	$0.50 to $0.74.	$0.75 to $0.99.	$1.00 to $1.24.	$1.25 to $1.49.	$1.50 to $1.74.	$1.75 to $1.99.	$2.00 to $2.24.	$2.25 to $2.49.	$2.50 to $2.74.	$2.75 to $2.99.	$3.00 to $3.24.	$3.25 to $3.49.	$3.50 to $3.74.	$3.75 to $3.99.	$4.00 to $4.24.	$4.25 and over.
Engineers																	
Firemen																	
Machinists, blacksmiths, carpenters, and other mechanics																	
Miners																	
Miners' helpers																	
Timbermen and track layers																	
Boys under 16 years																	
All other employees, not including those on salaries																	

AVERAGE NUMBER OF WAGE-EARNERS EMPLOYED DURING EACH MONTH.

MONTH.	Men 16 years and over.	Boys under 16 years.	MONTH.	Men 16 years and over.	Boys under 16 years.
January			July		
February			August		
March			September		
April			October		
May			November		
June			December		

(Only wage-earners should be reported, including miners working on tonnage and other pieceworkers. Do not include firm members, general officers, superintendents, managers, foremen, clerks, and other salaried employees.)

4. If mining is paid for by ton, car, yard, or other unit, give rate paid and character of unit, ...

Average number of employees engaged in this class of mining, ...

Total amount paid for such work, $.....

Amount paid as yardage or other allowances to miners, if any, $.....

(The rate paid for mining not done by the day should be reported, and the number of employees engaged in such work and the total amount paid. If yardage or other allowances are made to miners in consideration of difficult mining, narrow work, or for other causes, the total amount paid as such during the year should be reported under this inquiry.)

Inquiries 5, 6, 7, and 8, same as Schedule No. 6.

9. Product:

Total quantity of marketable coal mined during the year, ...

Total value at mine, $.....

Number of mine cars of coal, run of mine, hoisted during the year, ...

Average capacity of mine cars, in pounds, ...

(Under this inquiry should be reported the quantity and value of all coal mined during the year, f. o. b. at mine, as reported to the United States Geological Survey. The number of cars loaded in the mine with their average capacity, in pounds, should also be reported.)

Inquiry 10, same as Schedule No. 6.

11. What mechanical system of haulage is employed, if any—tail rope, endless rope, electric locomotive, compressed air, or other kind? .....

12. Are automatic slate pickers or coal cleaners used in the breaker? .....
(Does not apply to bituminous coal mines.)

13. Number of washeries at this colliery, if any, ..., and price per ton charged to washeries for culm, ...
(Does not apply to bituminous coal mines.)

14. Nature of openings to the works—shaft, slope, drift or level, open cutting or stripping, or other method, and depth or length in feet of each, ...

15. System of ventilation in use—fan, furnace, fire basket, exhaust steam, natural, or other kind, ...

16. If coal was mined on royalty during the year, give the rate per ton paid, ...

In addition to Special Schedule No. 8 for coal mines of a commercial character, there was provided for small country coal banks to which Special Schedule No. 8 could not be applied a simpler form of combined letter and schedule.

Schedule for small coal banks.

DEPARTMENT OF THE INTERIOR,
UNITED STATES GEOLOGICAL SURVEY,
Washington, D. C., June 1, 1903.

DEAR SIR: In accordance with the act of Congress of March 6, 1902, requiring the Director of the Census to prepare a report on mines and quarries, and pursuant to an agreement between the Director of the Census and the Director of the United States Geological Survey, the Geological Survey will collect the data for the mining census, in addition to the usual information collected for the annual report, "Mineral Resources of the United States." The schedule below has been prepared for the purpose of obtaining the statistics of the production of small coal banks which are engaged in mining coal for immediate local consumption. Please fill out the replies to all the inquiries and return this schedule in the accompanying envelope, which requires no postage.

In order that reports from all local banks may be secured, and the canvass thus be made as complete as possible, you are requested to add the names of the owners of any other mines in your immediate vicinity.

Your prompt compliance with this request will greatly facilitate the work of both the Geological Survey and the Census Office, and will be highly appreciated.

Very respectfully,

CHAS. D. WALCOTT, *Director.*

Name.....
Post office.....
County.....
State.....

Quantity of coal produced in 1902:

Tons..... .....
Bushels..... .....
Total value of the same at the mine ..... $.....
Total cost of supplies and materials used at the mine in 1902.... $.....
Total amount paid in wages during the year ..... $.....
Total number of men employed at the mine during the year... ... .
Total number of days the mine was worked during the year... .....

Please give below the names of owners of other small coal mines in your vicinity. Other names may be added on the back of this sheet.

NAME.	Post office.	State.

Special Schedule No. 9.—For petroleum and natural gas wells. (*Number printed, 20,000.*)

First page same as Schedule No. 6.

Inquiries 1 and 2 same as Schedule No. 6.

3. Persons employed:

CLASSES.	Average number employed during the year.	Total amount paid in wages or salaries during the year.
General officers		$.....
Superintendents, managers, foremen, etc		
Clerks		
Engineers, firemen, machinists, blacksmiths, drillers, rig builders, pumpmen, and other mechanics		
Boys under 16 years		
All other employees		
Total		$.....

(Account for all persons employed at the wells. Give the total salaries and wages paid, which should include board or rent furnished as part compensa-

tion. Stockholders of corporations are not to be reported unless they are salaried officials. Amounts paid for contract work, not done by employees hired directly, and the number employed in such work, must not be included in this inquiry, but be reported in answer to Inquiry 5. The average number employed during the year is the number that would be required, at continuous employment for the twelve months, to produce the quantity of product reported.)

AVERAGE NUMBER OF WAGE-EARNERS AT SPECIFIED DAILY RATES OF PAY.

OCCUPATIONS.	Less than $0.50.	$0.50 to $0.74.	$0.75 to $0.99.	$1.00 to $1.24.	$1.25 to $1.49.	$1.50 to $1.74.	$1.75 to $1.99.	$2.00 to $2.24.	$2.25 to $2.49.	$2.50 to $2.74.	$2.75 to $2.99.	$3.00 to $3.24.	$3.25 to $3.49.	$3.50 to $3.74.	$3.75 to $3.99.	$4.00 to $4.24.	$4.25 and over.
Engineers and pumpmen																	
Firemen																	
Machinists, blacksmiths, drillers, rig builders, and other mechanics																	
Boys under 16 years																	
All other employees, not including those on salaries																	

AVERAGE NUMBER OF WAGE-EARNERS EMPLOYED DURING EACH MONTH.

MONTH.	Men 16 years and over.	Boys under 16 years.	MONTH.	Men 16 years and over.	Boys under 16 years.
January			July		
February			August		
March			September		
April			October		
May			November		
June			December		

(Only wage-earners should be reported. Do not include firm members, general officers, superintendents, managers, foremen, clerks, and other salaried employees.)

Inquiry 4 same as Inquiry 5 on Schedule No. 6.

5. Contract work:
Amount paid, if any, for well drilling, rig building, etc., if not done by employees hired directly by this establishment, $.....

Average number of men employed on such work.....

Number of days employed.....

6. Supplies and materials:
Total cost of supplies and materials of all kinds used during the year, including freight paid on the same, $.....

(The actual cost of all supplies and materials used during the year, including freight paid on the same, must be reported. The cost of the following materials should be reported under this inquiry: Lumber and timber used for repairs, rig building, and all other purposes; iron and steel for blacksmithing; parts of machinery and tools used for renewals and repairs; explosives, water for boilers and for other purposes, fuel, machinery supplies, etc.)

7. Miscellaneous expenses:

ITEMS.	Amount.
Royalties and rent of wells	$.....
Amount paid for rent of offices, taxes, insurance, interest, advertising, office supplies, law expenses, telegraph and telephone service, and all other sundries not reported elsewhere	.....
Total	$.....

(All items of expense incident to the operation of the wells not accounted for under Inquiries 3, 5, and 6, must be reported here. Do not include any portion of the freight reported under Inquiry 6 as paid on supplies and materials.)

8. Product:
Total quantity of petroleum produced during the year (barrels of 42 gallons).....

Total value, at wells, of petroleum produced during the year..... $.....

Total value, at wells, of natural gas produced during the year..... $.....

(Under this inquiry should be reported the quantity and value of petroleum and the value of natural gas produced during the year, at the wells, as reported to the United States Geological Survey.)

Inquiry 9 same as Inquiry 10 on Schedule No. 6.

10. Tankage:
Number of tanks at wells .....; total capacity, in barrels of 42 gallons .....

11. Wells:
Total number of wells drilled during the year .....; number of producing wells drilled during the year .....; number of dry holes drilled during the year .....

Of the total number of wells reported on this schedule, state the number flowing .....; number pumping .....; and the number abandoned during the year, ...

What diminution of pressure has occurred during the year? (Describe fully.)

Special Schedule No. 10.—For gold, silver, lead, and copper mines. (*Number printed, 78,000.*)

First page same as Schedule No. 6, except that the following note of instructions is printed after the location and post office address of the mine:

Where a mine and reduction works are operated under the same management, separate reports should be made on each Schedule No. 10 and No. 11, respectively. If this is not possible, a full report should be made on this schedule (with the exception of Inquiry 10), covering both the mine and reduction works, and answers should also be given to Inquiries 4, 5, 9, 10, and 12 on Schedule No. 11.

Inquiry 1 same as Schedule No. 6.

2. If this mine was ever abandoned, state year when last abandoned ..... and when last reopened .....

Inquiries 3, 4, 5, and 6, same as Inquiries 2, 3, 4, and 5, on Schedule No. 6.

7. Contract work:
a. Amount paid, if any, for work not done by employees hired directly by this establishment, $.....

State whether drainage, pumping, tunneling, shaft sinking, boring test holes, etc.....

Average number of men employed on such work.....

Number of days employed.....

b. Total amount received for contract work done for other establishments, $..... State whether tunneling, drainage, pumping, etc.....

(Do not include charges for treatment of ores, tailings, etc., at custom mills.)

Inquiry 8 same as Inquiry 7 on Schedule No. 6.

9. Miscellaneous expenses:

ITEMS.	Amount.
Amount expended in development work	$.....
Rent and royalties of mine and mineral land	.....
Rent of mining plant and improvements	.....
Rent or royalty for tunnel privileges	.....
Water rent	.....
Other rent or royalties (specify kind)	.....
Amount paid for taxes, insurance, interest, advertising, office supplies, law expenses, injuries and damages, telegraph and telephone service, gas, and all other sundries not reported elsewhere	.....
Total	$.....

(All items of expense incident to the operation of the mine, not accounted for under Inquiries 4, 5, 7, and 8, must be reported here. Do not include any portion of the freight reported under Inquiry 8 as paid on supplies and materials. The items of rent should be stated separately only in cases where they

are paid separately; if any two or more of them are paid in one sum, for instance royalties for mine and mining plant, the fact should be stated and the one amount paid should be given, without attempting to make a division.)

10. Product:
Gross value of metallic contents, as reported to the United States Geological Survey ..... $.....
Deductions:
Charges for treatment, per ton, $.....; total ..... $.....
Freight, per ton, $.....; total ..... $.....
Net value of mining product ..... $.....

11. Name and address of mill or works at which the ore is treated, ...
By what method is the ore conveyed from the mine to the mill? .....

12. Mineral lands:
Total acreage—owned ....; held on lease ....; leased to other parties .....
If worked by dredges, state total area treated in 1902, acres .....

13. Water plant:
Total length of ditches owned (including flumes, pipes, etc.), miles, ...; feet, ...

14. Length of railroad tracks owned:
On the surface .....
Underground .....

Inquiry 15 same as Inquiry 10 on Schedule No. 6.

16. Machinery:

CLASS OF MACHINE.	Kind of power.	Number.
Hoisting engines		
Pumping engines		
Locomotives for outside or inside haulage		
Power drills		
Steam shovels or derricks		
Dredges		

Special Schedule No. 11.—For reduction works (*other than smelters*). (*Number printed, 11,500.*)

First page same as Schedule No. 6.

Inquiries 1 and 2 same as Schedule No. 6.

3. Persons employed:

CLASSES.	Average number employed during the year.	Total amount paid in wages or salaries during the year.
General officers		$.....
Superintendents, managers, foremen, assayers, etc.		
Clerks		
Engineers, firemen, machinists, blacksmiths, carpenters, and other mechanics		
Boys under 16 years		
All other employees		
Total		$.....

(Account for all persons employed at the works. Give the total salaries and wages paid, which should include board or rent furnished as part compensation. Stockholders of corporations are not to be reported unless they are salaried officials. The average number employed during the year is the number that would be required, at continuous employment for the twelve months, to produce the quantity of product reported.)

AVERAGE NUMBER OF WAGE-EARNERS AT SPECIFIED DAILY RATES OF PAY.

OCCUPATIONS.	Less than $0.50.	$0.50 to $0.74.	$0.75 to $0.99.	$1.00 to $1.24.	$1.25 to $1.49.	$1.50 to $1.74.	$1.75 to $1.99.	$2.00 to $2.24.	$2.25 to $2.49.	$2.50 to $2.74.	$2.75 to $2.99.	$3.00 to $3.24.	$3.25 to $3.49.	$3.50 to $3.74.	$3.75 to $3.99.	$4.00 to $4.24.	$4.25 and over.
Engineers																	
Firemen																	
Machinists, blacksmiths, carpenters, and other mechanics																	
Boys under 16 years																	
All other employees, not including those on salaries																	

AVERAGE NUMBER OF WAGE-EARNERS EMPLOYED DURING EACH MONTH.

MONTH.	Men 16 years and over.	Boys under 16 years.	MONTH.	Men 16 years and over.	Boys under 16 years.
January			July		
February			August		
March			September		
April			October		
May			November		
June			December		

(Only wage-earners should be reported. Do not include firm members, general officers, superintendents, managers, foremen, clerks, and other salaried employees.)

Inquiry 4 same as Inquiry 5 on Schedule No. 6.

5. Amount paid, if any, for treatment of bullion, concentrates, tailings, or other products at custom smelters, refineries, or other custom works, $.....
Total freight paid on the same, $.....

6. Materials:
State character of materials used, whether ore, tailings, or other materials, ...

Total assay contents and value of all materials bought in 1902:

	Total assay contents.	Value.		Value.
Gold, ounces fine		$.....	Total gross value (brought forward)	$.....
Silver, ounces fine			Deductions:	
Lead, pounds			Total working charges	$.....
Copper, pounds			Total freight	$.....
Other metals, pounds			Total deductions	$.....
Total gross value		$.....	Net paid	$.....

(Under this inquiry should be given the cost of all materials bought for the mill. State the metallic contents of the ore, etc., as per sample or assay; the value allowed for gold, silver, lead, copper, and other metals contained in the materials; the deductions made to cover working charges and freight; and give the total net amount paid. Do not give under this inquiry the yield in gold, silver, and other metals resulting from the treatment of the materials at the works and reported to the Geological Survey.)

7. Supplies:
Total cost of mill supplies of all kinds used during the year, including freight paid on the same, $.....

(The cost of the following supplies should be reported under this inquiry: Shoes, dies, screens, plates, and other parts of machinery and tools used for renewals and repairs; quicksilver, cyanide of potassium, lumber, iron, steel, oil, fuel, water, etc.)

8. Miscellaneous expenses:
Amount paid for rent of offices, plant, and land, taxes, insurance, interest, advertising, office supplies, law expenses, injuries and damages, telegraph and telephone service, gas, and all other sundries not reported elsewhere, $.....

(All items of expense incident to the operation of the works, not accounted for under Inquiries 3, 5, 6, and 7, must be reported here. Do not include freight.)

9. Product:
Gross value of metallic contents, as reported to the United States Geological Survey ..... $.....

Deductions on product sold (not including product of this establishment treated at custom works):

Total smelter charges ..... $.....

Total freight ..... $.....

Net value of milling product at the mill ..... $.....

10. Custom work done by this establishment:

	Ore.	Concentrates or other material.	Tailings.	Total.
Quantity treated, tons				
Amount received, not including freight	$.....	$.....	$.....	$.....
Freight paid on the same	$.....	$.....	$.....	$.....

Inquiry 11 same as Inquiry 10 on Schedule No. 6.

12. Name, location, and character of establishment to which the product was sold or shipped for final treatment:
Gold bullion.....
Silver bullion .....
Concentrates .....
Other products (specify kind).....

In addition to the foregoing schedules, Nos. 10 and 11, for mines and reduction works, a schedule was printed for smelters and refineries. Smelters and refineries were included in the Census of Manufactures taken in 1900 and did not come within the scope of the Census of Mines and Quarries of 1902. This schedule was provided for the purpose of merely verifying the reports of the metallic contents of the ores mined and the cost of reduction, and of ascertaining the terms upon which ores were treated by custom smelters, the cost of smelting and refining, and the percentage of metals recovered in the process.

Special schedule No. 12.—For smelters and refineries. (*Number printed 1,000.*)

UNITED STATES CENSUS OFFICE.
Special Schedule No. 12.

DIVISION OF MANUFACTURES.
S. N. D. NORTH, Chief Statistician.

SMELTERS AND REFINERIES.

Name of works.....

Character of works.....

Name of company, firm, or individual owner.....

Location of works: City or town .....; County.....; State.....

General office at.....

Isaac A. Hourwich, Ph. D., of Washington, D. C., has been appointed expert special agent of the Census Office for this branch of the inquiry.

1. Date of establishment of works: .....

2. If a corporation, in which state incorporated? .....
Year of organization .....

3. Schedule of prices paid for materials treated in 1902:

	Ores.	Concentrates.	Matte.	Bullion.	Miscellaneous.
Gold, per ounce	$.....	$.....	$.....	$.....	$.....
Silver, percentage paid					
Lead, per unit (state what unit)	$.....	$.....	$.....	$.....	$.....
Lead, percentage paid					
Copper, per unit (state what unit)	$.....	$.....	$.....	$.....	$.....
Other metals (specify each kind)					
Deductions:					
Working costs, per ton	$.....	$.....	$.....	$.....	$.....
Freight, per ton					

Specify classes of materials embraced under the head of "Miscellaneous": ....

(State separately prices paid per ounce of gold contained in ores, concentrates, matte, bullion, or other materials; likewise state separately percentage of silver contents paid for in each class of materials, give the unit of lead and copper paid for, whether pound or percentage, contained in ore, concentrates, etc. If working costs per ton vary with the character of ore, give all rates in detail.)

4. If the smelter is in a mining district, state by what method the ore is conveyed from the mine to the smelter: .....

5. Total daily capacity of plant, tons per 24 hours: .....

6. Time in operation:
Total number of days in operation during the year 1902, ...; number of hours in operation per day .....

7. Total amount paid in salaries and wages during the year 1902, $.....

8. Cost of supplies used during the year, including freight paid on the same, $.....

(The cost of the following supplies should be given under this inquiry: Parts of machinery and tools used for renewals and repairs, fuel, fluxes, zinc, oil, and all other supplies consumed in the running of machinery.)

9. Miscellaneous expenses, $.....

(Amount paid for rent of land, buildings, machinery, offices, taxes, insurance, interest, advertising, office supplies, law expenses, injuries and damages, telegraph and telephone service, gas, and all other sundries not reported elsewhere.)

10. Production of smelter, not including custom work:

MATERIALS TREATED.	Ores.	Concentrates.	Matte.	Bullion.	Miscellaneous.
Quantity, tons or pounds					
Total contents as per assay before smelting:					
Gold, ounces fine					
Silver, ounces fine					
Lead, pounds					
Copper, pounds					
Other metals, pounds (specify each kind)					

BULLION RECOVERED.	From ores.	From concentrates.	From matte.	From bullion.	From miscellaneous.
Gold, ounces fine					
Silver, ounces fine					
Lead, pounds					
Copper, pounds					
Other metals, pounds (specify each kind)					

Specify classes of materials embraced under the head of "Miscellaneous":....

(Give the total quantity, in tons or pounds, of each class of materials treated and the assay contents of ores, concentrates, matte, bullion, etc., separately; also the bullion recovered from each class of materials—that is, the gold, silver, lead, copper, or other metallic contents of the smelted product, as shown by assay.)

11. Production of refinery, not including custom work:

	CRUDE BULLION TREATED.		Refined bullion produced, fine weight.
	Gross weight.	Fine weight as shown by assay.	
A. Materials from smelting department:			
Gold, ounces			
Silver, ounces			
Lead, pounds			
Copper, pounds			
Other products, pounds (specify each kind)			
B. Materials bought:			
Gold, ounces			
Silver, ounces			
Lead, pounds			
Copper, pounds			
Other products, pounds (specify each kind)			

12. Custom smelting: (See instructions under Inquiry 10.)

MATERIALS TREATED.	Ores.	Concentrates.	Matte.	Bullion.	Miscellaneous.
Quantity, tons or pounds					
Total contents as per assay before smelting:					
Gold, ounces fine					
Silver, ounces fine					
Lead, pounds					
Copper, pounds					
Other metals, pounds (specify each kind)					

BULLION RETURNED.	From ores.	From concentrates.	From matte.	From bullion.	From miscellaneous.
Gold, ounces fine					
Silver, ounces fine					
Lead, pounds					
Copper, pounds					
Other metals, pounds (specify each kind)					
Total smelting charges	$	$	$	$	$
Total freight charges					

Is freight charged to the customer?.....

Specify classes of materials embraced under the head of "Miscellaneous":....

13. Custom refining:

	CRUDE BULLION TREATED.		Refined bullion returned (fine weight).	Total tolls received.	Total freight charged.
	Gross weight.	Fine weight as per assay.			
Gold, ounces				$	$
Silver, ounces					
Lead, pounds					
Copper, pounds					
Other metals, pounds (specify each kind)					

14. Crude bullion treated at other refineries:

	CRUDE BULLION SHIPPED.		Refined bullion received (fine weight).	Total tolls paid.	Total freight paid.
	Gross weight.	Fine weight as per assay.			
Gold, ounces				$	$
Silver, ounces					
Lead, pounds					
Copper, pounds					
Other metals, pounds (specify each kind)					

15. Crude bullion sold:

	Gross weight.	Fine contents.	Total gross value.	Refining charges.	Freight charges.
Gold, ounces			$	$	$
Silver, ounces					
Lead, pounds					
Copper, pounds					
Other metals, pounds (specify each kind)					

16. Name and location of mint, assay office, or refinery to which bullion was shipped during the year:

Gold.....

Silver.....

Lead.....

Copper.....

Before commencing the mining census it was considered necessary to prepare a schedule for corporations, firms, or individuals operating more than one mine or quarry with a central office for all of them.

Special schedule, No. 6a.—Supplemental schedule for administrative and general offices. (*Number printed, 12,000.*)

Name of company, firm, or individual owner .....

General office: State.....; County.....; City or town .....

Corporations, firms, or individuals operating more than one mine, quarry, or reduction works, with a central office for all of them, are requested to report on this schedule the employees of such central office, with their salaries or wages, and all other employees whose work is not confined to one particular mine, quarry, or reduction works, such as general superintendents, machinists, surveyors, etc. All general expenses are also to be reported on this schedule, and the data relating to capital stock, bonds, dividends, and assessments of incorporated companies. No data reported on this schedule should appear on the separate reports for the individual mines, quarries, or reduction works. Separate schedules are supplied for these individual plants.

CERTIFICATE.

This is to certify that the information contained in this schedule is complete and correct to the best of my knowledge and belief.

.....
(Signature and official designation of the person furnishing the information.)

.....
(Signature of special agent.)

1. Character of present organization, whether individual, firm, limited partnership, cooperative association, or incorporated company: .....

2. Capital stock, bonds, dividends, and assessments (if an incorporated company):

	BONDS.		PREFERRED STOCK.		COMMON STOCK.	
	Number.	Total par value.	Number of shares.	Total par value.	Number of shares.	Total par value.
Authorized		$.....		$.....		$.....
Issued to end of the year		$.....		$.....		$.....

Dividends and interest, if any, paid during the year:
Common stock, rate ..... ; amount, $.....
Preferred stock, rate ..... ; amount, $.....
Bonds, rate ..... ; amount, $.....
Assessments: Total amount levied since organization of company.. $.....

3. Persons employed:

CLASSES.	Average number employed during the year.	Total amount paid in salaries or wages during the year.
General officers		$.....
Other officers (managers, general superintendents, etc.)		
Clerks		
Surveyors, machinists, laborers, and all others not employed at particular mines, quarries, or reduction works		
Total		$.....

(Account for all persons not included in the separate returns for mines, quarries, or reduction works. Give the total salaries and wages paid, which should include board or rent furnished as part compensation. Stockholders of corporations are not to be reported, unless they are salaried officials. Amounts paid for contract work, not done by employees hired directly, and the number employed in such work, must not be included in this inquiry, but be reported in answer to Inquiry 4. The average number employed during the year is the number that would have continuous employment for the twelve months.)

4. Contract work:
Amount paid, if any, for tunneling, shaft sinking, boring test holes, etc., not chargeable to a particular mine or quarry, if not done by employees hired directly by this establishment ..... $.....
Average number of men employed on such work.....
Number of days employed.....

5. Miscellaneous expenses:
Amount paid for rent of offices, taxes, insurance, interest, advertising, office supplies, law expenses, injuries and damages, telegraph and telephone service, gas, and all other sundries not reported elsewhere ..... $.....

(All items of general expense not accounted for under Inquiries 3 and 4 must be reported here.)

6. Names and locations of mines, quarries, or reduction works owned or leased: (If not sufficient space, use separate sheet of paper.)

NAME OF MINE, QUARRY, OR REDUCTION WORKS.	LOCATION. State.	County.	Nearest city or town.

Special Schedule No. 6b.—For stone quarries in addition to Special Schedule No. 6, as supplementary thereto. (*Number printed, 35,000.*)

UNITED STATES CENSUS OFFICE.

Special Schedule No. 6b.

(To be filled out and returned in connection with and in addition to Special Schedule No. 6, as supplementary thereto.)

DIVISION OF MANUFACTURES.
S. N. D. NORTH, Chief Statistician.

STONE QUARRIES.

Name of quarry .....
Kind of stone .....
Name of company, firm, or individual owner .....
Location of quarry: State ..... ; County .....
Nearest city or town ..... ; Post office .....

Dr. G. P. Merrill, of the United States National Museum, has been appointed expert special agent of the Census Office for the collection of statistics relating to stone quarries.

QUARRYING AND STONE-DRESSING MACHINES.

(Please state the kinds of drills, channellers, gadders, and quarry bars used, and if other machines than those specified below are used, please report them and give full description in the blank spaces provided.)

KIND.	Trade name and make.	Number used.	Year when adopted.
Drills			
Channellers			
Gadders			
Quarry bars			
Helicoidal saws			
Reciprocating saws used with sand, chilled iron, or crushed steel, in gangs			
Reciprocating saws with diamond teeth			
Planers			
Lathes			
Rubbing beds			
Polishers			
Surfacing machines			
Jointing machines			
Sand-blast machines			
All others			

There were provided in addition to the schedules of the Census Office, copies of the schedules of the Geological Survey which were used for transcribing the information reported to that office.

No. .....

DIVISION OF MANUFACTURES.

MINES AND QUARRIES.

SLATE. (*Number printed, 300.*)

Special Schedule No. 6.

Name of quarry .....
Name of company, firm, or individual owner .....
General office .....
Location of quarry: State ..... ; County .....
Nearest city or town .....

1. Please give quantity of slate sold and selling value at the quarry for the year 1902, as follows:

[Give your usual unit of measurement, but state definitely what it is.]

	Quantity.	Value.
Roofing slate (squares)		$
Milling stock and all other purposes		
Total value		$

2. How was the demand and what was the general condition of trade in 1902 as compared with the preceding year?

Note carefully the following:

Unless statements of tests or analyses of your slate have been given with previous replies, you are earnestly requested to give the results of any such analyses or tests, with the name of the expert who made the analysis or test.

Please give the names and addresses of any new quarry operators in your vicinity.

If you have retired permanently from the business, or did not operate last year, please so state.

MARBLE. (*Number printed, 500.*)

Special Schedule No. 6.

Name of quarry .....

Name of company, firm, or individual owner .....

General office .....

Location of quarry: State .....; County .....

Nearest city or town .....

1. Please give quantity of marble quarried and the value at the quarry for the year 1902, as follows:

[Give your usual unit of measurement, but state definitely what it is.]

	Quantity.	Value.
Sold rough for—		
Building purposes		$
Monumental work		
Other purposes		
Dressed for—		
Building purposes		
Monumental work		
Ornamental purposes		
Interior decoration		
Other purposes		
Other uses		
[State use, if possible.]		
Total value		$

2. How was the demand and what was the general condition of trade in 1902 as compared with 1901?

Note carefully the following:

Unless statements of tests or analyses of your marble have been given with previous replies, you are earnestly requested to inclose the results of any such analyses or tests, with the name of the expert who made the analysis or test.

If you have retired permanently from the business, or have not operated in 1902, please so state.

If you have disposed of your quarry, please give the name and address of your successor and the date on which you sold.

If you have recently acquired your quarry, please give the name of its former owner and the date on which you took possession.

Please give the names and addresses of any new quarry operators in your vicinity.

TRAP ROCK. (*Number printed, 500.*)

Special Schedule No. 6.

Name of quarry .....

Name of company, firm, or individual owner .....

General office .....

Location of quarry: State .....; County .....

Nearest city or town .....

1. Please give quantity of trap rock quarried and the value at the quarry for the year 1902, as follows:

[Give your usual unit of measurement, but state definitely what it is.]

	Quantity.	Value.
Sold rough for building purposes		$
Dressed for building purposes		
Made into paving blocks		
Crushed stone for—		
Roadmaking (macadam, etc.)		
Railroad ballast		
Concrete, etc		
Rubble		
Riprap		
Other purposes		
[State purpose, if possible.]		
Total value		$

2. How was the demand and what was the general condition of trade in 1902 as compared with 1901?

Note carefully the following:

Unless statements of tests or analyses of your trap rock have been given with previous replies, you are earnestly requested to inclose the results of any such analyses or tests, with the name of the expert who made the analysis or test.

If you have retired permanently from the business, or have not operated in 1902, please so state.

If you have disposed of your quarry, please give the name and address of your successor, and the date on which you sold.

If you have recently acquired your quarry, please give the name of its former owner and the date on which you took possession.

Please give the names and addresses of any new quarry operators in your vicinity.

GRANITE. (*Number printed, 2,000.*)

Special Schedule No. 6.

Name of quarry .....

Name of company, firm, or individual owner .....

General office .....

Location of quarry: State .....; County .....

Nearest city or town .....

1. Please give quantity of granite quarried and the value at the quarry for the year 1902, as follows:

[Give your usual unit of measurement, but state definitely what it is.]

	Quantity.	Value.
Sold rough for—		
Building purposes		$
Monumental work		
Other purposes		
Dressed for building purposes		
Dressed for monumental work		
Dressed for interior decoration		
Made into paving blocks		
Curbing		
Flagging		
Crushed stone for—		
Roadmaking (macadam, etc.)		
Railroad ballast		
Concrete, etc		
Rubble		
Riprap		
Other purposes		
[State purpose, if possible.]		
Total value		$

2. How was the demand and what was the general condition of trade in 1902 as compared with 1901?

Note carefully the following:

Unless statements of tests or analyses of your granite have been given with previous replies, you are earnestly requested to inclose the results of any such analyses or tests with the name of the expert who made the analysis or test.

If you have retired permanently from the business, or have not operated in 1902, please so state.

If you have disposed of your quarry, please give the name and address of your successor and the date on which you sold.

If you have recently acquired your quarry, please give the name of its former owner and the date on which you took possession.

Please give the names and addresses of any new quarry operators in your vicinity.

SANDSTONE. (*Number printed, 1,750.*)

Special Schedule No. 6.

Name of quarry .....

Name of company, firm, or individual owner .....

General office .....

Location of quarry: State .....; County .....

Nearest city or town .....

1. Please give quantity of sandstone quarried and the value at the quarry for the year 1902, as follows:

[Give your usual unit of measurement, but state definitely what it is.]

	Quantity.	Value.
Sold rough for building purposes		$
Dressed for building purposes		
Crushed stone for—		
Roadmaking (macadam, etc.)		
Railroad ballast		
Concrete, etc		
Ganister rock		
Riprap		
Rubble		
Paving		
Flagging		
Curbing		
Grindstones		
Whetstones		
Sand mined:		
Glass sand		
Engine sand		
Furnace sand		
Building sand		
Other uses		
Other purposes [State purpose, if possible.]		
Total value		$

2. How was the demand and what was the general condition of trade in 1902 as compared with 1901?

Note carefully the following:

Unless statements of tests or analyses of your sandstone have been given with previous replies, you are earnestly requested to inclose the results of any such analyses or tests, with the name of the expert who made the analysis or test.

If you have retired permanently from the business or have not operated in 1902, please so state.

If you have disposed of your quarry, please give the name and address of your successor, and the date on which you sold.

If you have recently acquired your quarry, please give the name of its former owner and the date on which you took possession.

Please give the names and addresses of any new quarry operators in your vicinity.

BLUESTONE. (*Number printed, 500.*)

Special Schedule No. 6.

Name of quarry .....

Name of company, firm, or individual owner .....

General office .....

Location of quarry: State .....; County .....

Nearest city or town .....

1. Please give quantity of bluestone quarried and the value at the quarry for the year 1902, as follows:

[Give your usual unit of measurement, but state definitely what it is.]

	Quantity.	Value.
Sold rough for building purposes		$
Dressed for building purposes		
Crushed stone for—		
Roadmaking (macadam, etc.)		
Railroad ballast		
Concrete, etc		
Riprap		
Rubble		
Paving		
Flagging		
Other purposes [State purpose, if possible.]		
Total value		$

2. How was the demand and what was the general condition of trade in 1902 as compared with 1901?

Note carefully the following:

Unless statements of tests or analyses of your bluestone have been given with previous replies, you are earnestly requested to inclose the results of any such analyses or tests, with the name of the expert who made the analysis or test.

If you have retired permanently from the business, or have not operated in 1902, please so state.

If you have disposed of your quarry, please give the name and address of your successor and the date on which you sold.

If you have recently acquired your quarry, please give the name of its former owner and the date on which you took possession.

Please give the names and addresses of any new quarry operators in your vicinity.

LIMESTONE. (*Number printed, 7,500.*)

Special Schedule No. 6.

Name of quarry .....

Name of company, firm, or individual owner .....

General office .....

Location of quarry: State .....; County .....

Nearest city or town .....

1. Please give quantity of limestone quarried and the value at the quarry for the year 1902, as follows:

[Give your usual unit of measurement, but state definitely what it is.]

	Quantity.	Value.
Building purposes		$
Flagging		
Curbing		
Stone burned into lime		
Lime made [Give quantity and value of lime in bulk.]		
Stone sold as such to lime burners		
Crushed stone for—		
Roadmaking (macadam, etc.)		
Railroad ballast		
Concrete, etc		
Rubble		
Riprap		
Blast-furnace flux		
Quarried for cement		
Other purposes [State purpose, if possible.]		
Total value		$

2. What was the average price of lime per bushel or barrel in your locality during 1902?

3. How was the demand and what was the general condition of trade in 1902 as compared with 1901?

Note carefully the following:

Unless statements of tests or analyses of your limestone, or the lime made from it, have been given with previous replies, you are earnestly requested to inclose the results of any such tests or analyses, with the name of the expert who made the analysis or test.

If you have retired permanently from the business or have not operated in 1902, please so state.

If you have disposed of your quarry, please give the name and address of your successor, and the date on which you sold.

If you have recently acquired your quarry, please give the name of its former owner and the date on which you took possession.

Please give the names and addresses of any new quarry operators in your vicinity.

BARYTES. (*Number printed, 800.*)

Special Schedule No. 6.

Name of mine.....

Name of company, firm, or individual owner.....

General office .....

Location of mine: State .....; County .....

Nearest city or town .....

Inquiries for miners.

Quantity of crude barytes produced in 1902, short tons .....

Total value at the mine ..... $.....

[If any part of the above product was purchased from other parties, please state under "Remarks" the names of such parties and the quantity obtained from each.]

Inquiries for manufacturers.

Quantity of barytes treated by you in 1902, short tons .....

Quantity of refined product, as follows:

Floated for pigment, short tons .....

For canvasing hams, etc., short tons.....

For other purposes, short tons .....

Value of refined product..... $.....

Please state from what locality your crude material was obtained: .....

What was the tendency of trade as compared with preceding year?

Please note the names and addresses of any new operators in your vicinity.

REMARKS.

MINERAL PAINTS. (*Number printed, 1,000.*)

Special Schedule No. 6.

Name of mine or works .....

Name of company, firm, or individual owner .....

General office .....

Location of mine or works: State .....; County.....

Nearest city or town .....

Please fill out the following blanks with the quantity and value of your production in 1902. It is preferred to have returns made for "dry ground" paint. If you sell in any other condition, please state what it is.

	Quantity (short tons).	Value.
Metallic paint.....	.....	$.....
Mortar colors.....	.....	.....
Ocher	.....	.....
Umber	.....	.....
Sienna	.....	.....
Soapstone	.....	.....
Barytes.....	.....	.....
Slate	.....	.....
Venetian reds.....	.....	.....
Zinc white	.....	.....
Other pigments	.....	.....

Please note any changes in the condition of trade as compared with the preceding year.

Please give the names and addresses of any new operators in your vicinity.

REMARKS.

MICA. (*Number printed, 250.*)

Special Schedule No. 6.

Name of mine.....

Name of company, firm, or individual owner .....

General office .....

Location of mine: State.....; County .....

Nearest city or town .....

What was your production in 1902?

	Quantity.	Value.
Cut or sheet mica.....pounds..	.....	$.....
Scrap or waste .....short tons..	.....	.....

What were the uses for which it was sold? Please make an estimate if you have no exact figures.

USES.	Quantity.
Stove .....pounds..	.....
Electrical .....pounds..	.....
Ground for—	
Lubricants .....short tons..	.....
Wall papers.....short tons..	.....
Other purposes .....short tons..	.....

How many days was your mine worked in 1902?

Please note the names and addresses of any new operators in your vicinity.

REMARKS.

PHOSPHATE ROCK. (*Number printed, 1,250.*)

Special Schedule No. 6.

Name of mine .....

Name of company, firm, or individual owner.....

General office .....

Location of mine: State.....; County.....

Nearest city or town .....

What was the quantity and value of your product in 1902?

[Please state definitely whether long or short ton is used.....]

	Total quantity produced in 1902. .... tons.	Total quantity sold in 1902. .... tons.	Value of sales.
Land rock	.....	.....	$.....
River rock	.....	.....	.....
Hard rock.....	.....	.....	.....
Soft rock.....	.....	.....	.....
Plate rock.....	.....	.....	.....
Land pebble	.....	.....	.....
River pebble.....	.....	.....	.....
White rock.....	.....	.....	.....
Blue rock	.....	.....	.....
Brown rock.....	.....	.....	.....
Total.....	.....	.....	$.....

Answers to above queries are requested from *producers* of phosphate rock only. If the person addressed is a merchant or agent, buying and selling phosphates or phosphate lands, and not engaged in mining, please return this card with a statement to that effect.

Please give the names and addresses of any new operators in your vicinity.

REMARKS.

GYPSUM AND GYPSUM PRODUCTS. (*Number printed, 400.*)

Special Schedule No. 6.

Name of quarry .....

Name of company, firm, or individual owner.....

General office.....

Location of quarry: State.....; County .....

Nearest city or town .....

Source of gypsum.

	Short tons.	Value.
Quantity quarried		$
Quantity purchased locally		
Quantity imported		
Total value		$

Disposal of gypsum.

	Short tons.	Value.
Quantity sold crude		$
Quantity sold as land plaster		
Quantity sold as wall or cement plaster		
Quantity sold as plaster of Paris		
Total value		$

What was the condition of trade as compared with that of the preceding year?
Please note the names and addresses of any new operators in your vicinity, and add any other information which the blank does not furnish space for.

REMARKS.

EMERY AND CORUNDUM. (*Number printed, 100.*)

Special Schedule No. 6.

Name of mine

Name of company, firm, or individual owner

General office

Location of mine: State ; County

Nearest city or town

Emery.

	Short tons.
1. Total quantity of emery mined in 1902	
2. Total quantity of emery sold in 1902	
3. Total value of emery sold	$

Corundum.

	Short tons.
4. Total quantity mined in 1902	
5. Total quantity sold in 1902	
6. Total value of corundum sold	$

NEW ADDRESSES.

Please give the names of any other operators in your vicinity.

REMARKS.

MILLSTONES. (*Number printed, 100.*)

Special Schedule No. 6.

Name of quarry

Name of company, firm, or individual owner

General office

Location of quarry: State ; County

Nearest city or town

1. Total number of millstones made by you in 1902

2. Total number sold in 1902

3. Total value of millstones sold in 1902 $

4. Please state how many of each size you made and what was the average price per pair.

	Number made.	Price per pair.
30 inches		$
36 inches		
42 inches		
48 inches		

5. What was the condition of trade as compared with the previous year?

Please give the name and address of any new manufacturer of millstones in your vicinity.

REMARKS.

GRINDSTONES. (*Number printed, 150.*)

Special Schedule No. 6.

Name of quarry

Name of company, firm, or individual owner

General office

Location of quarry: State ; County

Nearest city or town

	Short tons.
1. Total approximate quantity of crude rock quarried in 1902 [This question applies only to stone quarried for the manufacture of grindstones.]	
2. Total number of grindstones made in 1902	
3. Total number of grindstones of your own make sold by you in 1902 [In replying to questions 2 and 3, please state definitely whether your product is sold by weight or otherwise.]	
4. Total value of grindstones sold in 1902	$

5. Please give average prices for different sizes of grindstones during the year. Please note the names of any other manufacturers in your vicinity.

REMARKS.

SOAPSTONE AND TALC. (*Number printed, 250.*)

Special Schedule No. 6.

Name of quarry

Name of company, firm, or individual owner

General office

Location of quarry: State ; County

Nearest city or town

Total quantity of {soapstone / talc} produced by you in 1902 (short tons)	
Quantity sold in rough state as quarried (short tons)	
Total value of same	$
Quantity sawed into slabs and sold (short tons)	
Total value of slabs sold	$
Quantity made by you into washtubs, laboratory or kitchen sinks, stove bricks, griddles, or other mill stock (short tons)	
Total value of manufactured articles	$
Quantity ground for paint, paper filling, complexion powders, lubricants, etc. (short tons)	
Value after grinding	$

Information regarding any further uses to which your product is put, the condition of trade, new developments, etc., will be greatly appreciated.
Please note the causes of any notable fluctuations, either in amount or value, of your production as compared with the preceding year. This should include fires or other accidents, strikes, new advantages in transportation facilities, favorable freight rates, etc.

BITUMINOUS COAL. (*Number printed 10,000.*)

Special Schedule No. 8.

Name of mine

Name of company, firm, or individual owner

General office

Location of mine: State ; County

Nearest city or town

Character of coal produced

Disposition of product: [Include all marketable sizes of coal. Exclude only slack coal wasted.] Tons.

Loaded at mines for shipment .....

Sold to local trade or used by employees .....

Used at mines for steam and heat .....

Made into coke at mines .....

Total production in 1902 .....

Please state definitely whether "long" or "short" ton is used by you .....

Total selling value of product ..... $.....

Average price per ton ..... $.....

Average number of full days made by each employee (exclusive of coke workers) during the year. (Parts of days should be reduced to equivalent in full days) .....

Average number of employees during the year, including all persons connected directly with the mine, but excluding coke workers .....

If the mine reported hereon was idle because of strikes in 1902, please state how many men were affected and how many days they were idle.

Ans.: Number of men on strike .....

Number of days idle .....

Date of strike: From ..... to .....

Mining machines.

Do you use any machines for mining coal? Ans.: .....

How many were in use in 1902? Ans.: .....

How many tons of your product were mined by machines in 1902? Ans.: .....

Kinds of machines used.

	Number.
Pick machines:	
Harrison	
Sullivan	
Ingersoll-Sargeant	
Other kinds	
Chain-breast machines:	
Jeffrey air	
Jeffrey electric	
Independent or Link-Belt	
Morgan-Gardner	
Morgan-Standard	
Other kinds	
Long wall:	
Jeffrey	
Sperry	
Lee	
Other kinds	

ANTHRACITE COAL. (*Number printed, 500.*)

Special Schedule No. 8.

Name of mine .....

Name of company, firm, or individual owner .....

General office .....

Location of mine: State .....; County .....

Nearest city or town .....

Disposition of product: Long tons.

Loaded at mine for shipment .....

Sold to local trade or used by employees .....

Used at mine for steam and heat .....

Total production in 1902 .....

Total selling value of product ..... $.....

Average price per ton ..... $.....

Railways over which product was shipped .....

Average number of full days made by each employee during the year. (Parts of days should be reduced to equivalent in full days.) .....

Average number of employees during the year, including all persons connected directly with the mine .....

If the mine reported hereon was idle because of strikes in 1902, please state how many men were affected and how many days they were idle.

Ans.: Number of men on strike .....

Number of days idle .....

Date of strike: From ..... to .....

REMARKS.

CLAY. (*Number printed, 750.*)

Special Schedule No. 6.

Name of mine .....

Name of company, firm, or individual owner .....

General office .....

Location of mine: State .....; County .....

Nearest city or town .....

☞ In compiling these statistics the amount of sales during the year 1902 is what is desired, not including clay burned by yourself. By "value" is meant the net price at the mine f. o. b. cars, wagons, or boats.

Clay mined and sold in 1902.

	Quantity (tons of 2,000 pounds).	Value.
Kaolin:		
Raw		$
Ground, washed, or prepared in any way		
Ball clay:		
Raw		
Ground, washed, or prepared in any way		
Fire clay:		
Raw		
Ground, washed, or prepared in any way		
Stoneware clay:		
Raw		
Ground, washed, or prepared in any way		
Pipeclay:		
Raw		
Ground, washed, or prepared in any way		
Terra cotta clay:		
Raw		
Ground, washed, or prepared in any way		
Miscellaneous clay (please give variety):		
Raw		
Ground, washed, or prepared in any way		
Total mined and sold by you in 1902		

[If there have been any analyses made of your clay which you have not already sent to this office, please inclose copies with this slip.]

Please give the color to which your clay burns.

If you are also engaged in the burning of clay, please so state.

If you have retired permanently from the business, or made no sales of clay in 1902, please so state.

If you have disposed of your mine, please give the name and address of your successor, and the date on which you gave possession.

If you have recently acquired your mine, please give the name of its former owner and the date on which you took possession.

Please give the names and addresses of the operators of any new clay mines in your neighborhood.

CEMENT. (*Number printed, 250.*)

Special Schedule No. 6.

Name of quarry .....

Name of company, firm, or individual owner .....

General office .....

Location of quarry: State .....; County .....

Nearest city or town .....

	Quantity.
Natural cement made in 1902 (barrels)	
Portland cement made in 1902 (barrels)	
Limestone quarried in 1902	
Limestone purchased in 1902	
Marl mined in 1902	
Marl purchased in 1902	
Slag cement made in 1902 (barrels)	

Please state how many kilns you use:

	Number.
Vertical	
Rotary	

Please give the location of your office.
Please give the location of your factory.
If your plant was idle during the past year, please state that fact.
If you have disposed of your business, or retired, please state such facts and give the name of your successor, if any.
Please give the names of any new cement works established or projected in your neighborhood.

PRECIOUS METALS AND DEEP MINES. (*Number printed, 35,000.*)

Special Schedule No. 10a.

Name of mine.....

Name of company, firm, or individual owner.....

General office.....

Location of mine: State.....; County.....

Nearest city or town.....

Mining district or region.....

Name and address of superintendent.....

Tons of 2,000 pounds.

1. Total quantity of ore mined in 1902.....
2. Total quantity of ore sold or treated in 1902.....
3. Stock of ore on hand December 31, 1901.....
   Stock of ore on hand December 31, 1902.....
4. Total bullion contents of above ore sold or treated in 1902:

	Fine ounces.	Value.
Gold		$
Silver		
	Pounds.	
Copper		
Lead		
Other metals		
Total value		$

5. What is the prevailing mineralogical character of your ore? [For instance, auriferous pyrite, argentiferous galena, copper glance passing into chalcopyrite, etc.]
6. What is the geological character of your deposit? [For instance, fissure vein in granite, blanket deposit in limestone, contact deposit between limestone and porphyry, etc.]
7. How is your mine opened, and what is the extent of the workings? [For instance, by vertical shaft —— feet deep, by tunnel —— feet long, etc.]
8. By what process or processes is your ore reduced to the metallic state? [Smelting, amalgamation, chlorination, cyaniding, etc.]
9. If returns are from a number of mines or mining claims operated under one direction or management, please give names and localities of the same.
10. If ores are treated at reduction works owned or operated by the company, please state the process:
    a. Concentration only.....
    b. Stamp mill and concentration.....
    c. Chlorination.....
    d. Cyanide.....
    e. Give any peculiarities in your process or mode of treatment.....
11. Bullion contents and gross value per ton of ore sold or treated:
    Gold, fine ounces.....
    Silver, fine ounces.....
    Copper, per cent.....
    Lead, per cent.....
    Other metals, per cent.....
    Aggregate gross value..... $.....
12. Increase or decrease of stock of ore on hand:

		Increase.	Decrease.
Quantity	Tons		
Estimated value	$		

16. Total estimated value of the mining product..... $.....

PRECIOUS METALS—REDUCTION WORKS AT MINES. (*Number printed, 25,000.*)

Special Schedule No. 11a.

Name of mine.....

Name of company, firm, or individual owner.....

General office.....

Location of mine: State.....; County.....

Nearest city or town.....

Mining district or region.....

Name and address of superintendent.....

Bullion produced or contained in concentrates from ore or tailings treated in 1902:

	Fine ounces.	Value.
Gold		$
Silver		
	Pounds.	
Copper		
Lead		
Other metals (designate them)		
	Tons	
Total quantity of products other than bullion		
Total value		$

State general character and capacity of mill. [For instance, 20-stamp wet crushing, amalgamation with plates, 2 Frue vanners, and settling tanks. Capacity, 30 tons per 24 hours.]

Give any peculiarities in your process or mode of treatment.

Sources of material treated in 1902.

If any or all of the ore or other material treated by you in 1902 was custom material or was purchased from other parties, please give below the sources of such ores and the average assay or total bullion value of each.

STATE.	County.	Tons.	VALUE.	
			Gold.	Silver.

1. Bullion contents and gross value per ton of ore mined and milled:
   Gold, fine ounces.....
   Silver, fine ounces.....
   Copper, per cent.....
   Lead, per cent.....
   Other metals, per cent.....
   Aggregate gross value..... $.....
2. Bullion contents, total and per ton, and value of product from purchased materials:

	PRODUCT.			Average assay contents before treatment, per ton.
	Total quantity.	Per ton.	Total value.	
	Fine ounces.	*Fine ounces.*		*Fine ounces.*
Gold			$	
Silver				
	Pounds.	*Per cent.*		*Per cent.*
Lead				
Copper				
Other metals				
Total gross value			$	$
Average value per ton				

3. Bullion contents of the product of custom materials:

	PRODUCT.		
	Total quantity.	Per ton.	Total value.
	Fine ounces.	*Fine ounces.*	
Gold			$
Silver			
	Pounds.	*Per cent.*

REMARKS.

Please give any statement as to character, analysis, markets, etc., of your petroleum that may be of interest to the general public and that you are willing should be published, such as the well record. What is the character of the oil? Can you give analysis? What is its color? What is the character of strata in which it is found? What does it yield in illuminants? Etc.

IRON ORE. (*Number printed, 1,100.*)

Special Schedule No. 6.

Name of mine .....

Name of company, firm, or individual owner.....

General office .....

Location of mine: State.....; County.....

Nearest city or town.....

A. Underscore character of iron ore produced, and if more than one of the following classes is mined give quantity of each:

Limonite, brown hematite, or bog ore ....
Red hematite, specular or fossil ore..... .....
Magnetic ore ....
Carbonate or black band ore ....

B. State total quantity of marketable iron ore mined or produced during the year ending December 31, 1902.

.....gross tons.
[If none, so state.]

Also stock of iron ore on hand at mine December 31, 1902.

.....gross tons
[If none, so state.]

C. Give total value on cars or carts at the mine of the iron ore produced during the year ending December 31, 1902.

$.....

REMARKS.

MANGANESE ORE. (*Number printed, 250.*)

Special Schedule No. 6.

Name of mine.....

Name of company, firm, or individual owner.....

General office .....

Location of mine: State .....; County .....

Nearest city or town.....

A. State total quantity of marketable manganese ore mined or produced during the year ending December 31, 1902.

..... gross tons.
[If none, so state.]

B. Also stock of manganese ore on hand at mine December 31, 1902.

..... gross tons.
[If none, so state.]

C. Give total value on cars or carts at the mine of the manganese ore produced during the year ending December 31, 1902.

$ .....

REMARKS.

MINOR MINERALS. (*Number printed, 2,500.*)

Special Schedule No. 6.

Name of mine .....

Name of company, firm, or individual owner .....

General office .....

Location of mine: State .....; County .....

Nearest city or town .....

Tons.

Total quantity (approximately) of crude mineral ore produced in 1902 ....

[Please state whether long ton of 2,240 pounds or short ton of 2,000 pounds is used as the unit.]

If the product (or any part of it) is sold in the crude state, please say how much was sold crude in 1902 ....

Total value of same ..... $.....

If the product (or any part of it) is subject to any process of concentration, reduction, or refining before being sold, please state briefly what the process is.

Tons.

How much of the product in 1902 was so treated? ....

Tons or pounds.

Total quantity of concentrated or refined product obtained in 1902 ....

Total value of refined product ..... $.....

Any further information regarding the condition of trade and prospects of the future will be appreciated.

Please give the names of any new operators in your vicinity.

REMARKS.

Answers to the following inquiries on mines and quarries schedules do not appear in the detailed tables:

Schedule No. 6.

Inquiry 4.—Contract mining: Method of payment, by ton, car, yard, etc. Number employed. Amount paid.

Inquiry 5.—Time in operation: Number of hours in operation during the year. Number of hours per day. Number of shifts of workmen. Number of hours to shift.

Inquiry 9.—Product: Quantity of stone quarried. (Quantities were variously reported in perches, cords, tons, cubic yards, cubic feet, etc.)

Schedule No. 8.—Coal.

Inquiry 4.—(Same as in Schedule No. 6.)

Inquiry 5.—(Same as in Schedule No. 6.)

Inquiry 9.—Product: Number of mine cars of coal hoisted during the year. Average capacity of mine cars in pounds.

Inquiry 11.—Mechanical system of haulage, whether tail rope, endless rope, electric locomotive, compressed air, or other kind. (*Anthracite only.*)

Inquiry 12.—Are automatic slate pickers or coal cleaners used? (*Anthracite only.*)

Inquiry 13.—Number of washeries at colliery, and price per ton charged to washeries for culm.

Inquiry 14.—Nature of openings to works, whether shaft, slope, drift, or level, etc., and depth or length in feet of each.

Inquiry 15.—System of ventilation in use—fan, furnace, fire basket, exhaust steam, natural, or other kind.

Inquiry 16.—Rate per ton paid for coal mined on royalty.

Schedule No. 9.—Petroleum and natural gas.

Inquiry 10.—Tankage: Number of tanks at wells and their total capacity in barrels of 42 gallons.

Inquiry 11.—Wells: Number of wells drilled during the year. Number producing. Number of dry holes. Of total number of wells reported, state number flowing. Of total number of wells reported, state number pumping. Number abandoned during the year. What diminution of pressure occurred during the year?

30223—04——70

APPENDIX B.

INSTRUCTIONS TO SPECIAL AGENTS.

MINES, QUARRIES, AND REDUCTION WORKS.

INSTRUCTIONS.

1. By an agreement between the Director of the United States Census and the Director of the United States Geological Survey, made to avoid a duplicate canvass of the mining and quarrying industry, and for other purposes, the Geological Survey will have supervision of the field work of the Census of Mines and Quarries. In accordance with this agreement, reports will be secured on both the Census Office schedules and the schedules of the Geological Survey for all mines, quarries, and reduction works in existence during the year 1902. The schedules for the two offices must be forwarded in the same envelope.

2. The agents will transmit all schedules promptly to the Geological Survey at Washington, D. C., unless specially instructed, as will sometimes be the case, to send them to the office of special agents of the Geological Survey in other places.

3. Agents are required to comply with all the regulations of the Census Office governing field work and to submit daily reports on the blanks prepared for that purpose. The names of establishments for which returns were secured, and also of those visited but for which reports were not obtained, must appear on the report for each day. The agents must, also, under "Remarks," state the character of the mineral for which they are securing reports and keep the office advised of the probable date on which they will complete their present assignment. Daily reports will be promptly transmitted to the Census Office through the Geological Survey and the relative efficiency of each agent determined therefrom.

4. Each agent will be furnished with a list giving the names, locations, and addresses of all mines, quarries, etc., assigned to him, which were in existence during the year ending December 31, 1902, together with a list of those for which returns have been obtained by correspondence. This list has been prepared from reports made to the United States Geological Survey in previous canvasses, amended by information received from other sources. The list, however, may not be entirely complete, and the agent, therefore, must be constantly on the alert to discover other mines or quarries. They must make careful inquiry at each city and town they visit for mines and quarries located in that vicinity. If such plants are discovered, and they are located in the territory assigned the agent, he should proceed to secure returns for them in the same manner that reports are secured from establishments on the lists. In forwarding the reports for unlisted mines or quarries, the agent must call attention to the fact that the establishments do not appear on the list furnished him.

5. The agent is required to visit the different localities in the order in which they are named on the list, unless he finds that railroad connections and local conditions make a change necessary. In such cases the condition and character of the change must be stated on the agent's daily report.

6. In all cases where an annual report of the establishment is printed, a copy of the latest report should be secured and forwarded with the schedule. Copies should also be returned of any other printed matter that will add to the information contained in the schedule.

7. In case a mine or quarry is owned by a company with an office in another locality, outside the territory of the agent, and it is impossible to secure a complete report at the plant, the agent must complete the schedule as far as possible from the data obtainable at the mine, and forward it to the Geological Survey with a full statement of the facts, giving also the names and addresses of the persons from whom further information may be obtained.

8. It is important that a separate return be made for each mine or quarry and that the statistics of employees, wages, expenses, and supplies entered on the schedule pertain only to the mine or quarry reported. This rule should be observed in all branches of mining and quarrying, except petroleum and natural-gas wells, where all the wells located in a certain group or district under one ownership should be reported upon the same schedule.

9. However, if more than one mine or quarry in the same county is owned by the same company or firm, and it is impracticable to make a separate report for each, a combined report may be made which will include the operations of all. Mines or quarries under the same ownership in different counties must be reported on separate schedules. If a schedule includes the operations of more than one mine or quarry, a memorandum giving the name and post office address of each mine or quarry included should be attached to the schedule.

10. All entries in the schedule must be made clearly and neatly in ink. Quantities and values must be obtained from book accounts, if such accounts are available. *Each question is to be answered.* If any question is found not applicable, and no amounts are reported, write the word "None."

11. An exact answer to each item enumerated in the several questions is what is required, and is what should be given if it can be secured with a reasonable amount of labor. In all cases where the answers are estimated the amounts must be preceded by the word "Estimate."

Census Schedules.

12. Reports must be secured for all mines and quarries and for reduction works engaged in reducing the ores containing the precious metals. The schedules on which these reports are to be made are seven in number, as follows:

13. Special Schedule No. 6. All mines and quarries must be reported on this schedule except those for which special schedules are provided. Mines and quarries of the following minerals are to be reported on this schedule: Bluestone, granite, limestone, marble, sandstone, slate, trap rock, grindstones, millstones, soapstone and talc, cement rock, clay, barytes, emery and corundum, gypsum,

mica, mineral paints, phosphate rock, iron ore, and manganese ore. Special attention is called to the fact that on this schedule also (Special Schedule No. 6) should be reported the nonargentiferous or soft-lead mines located east of the Rocky mountains, the copper mines of the Lake Superior region, and zinc mines. Other minerals, mined as such, to be reported on this schedule except where they accompany minerals of more importance, as platinum in gold placers, are the following: Antimony, asbestos, asphaltum, bauxite, borax, chrome ore, cobalt, feldspar, fibrous talc, flint, fluorspar, fuller's earth, garnet, graphite, infusorial earth and tripoli, magnesite, marls, molybdenum, monazite, oilstones, platinum, precious stones, pyrite, crystalline quartz, quicksilver, rutile, sulphur, tungsten, uranium, and vanadium.

14. Special Schedule No. 8, for Coal Mines, both anthracite and bituminous, and anthracite coal washeries.

15. Special Schedule No. 9, for Petroleum and Natural-Gas Wells.

16. Special Schedule No. 10, for Gold and Silver, and argentiferous and auriferous Lead and Copper Mines.

17. Special Schedule No. 11, for Reduction Works of the precious metals (other than Smelters and Refineries).

18. Special Schedule No. 6a, a supplemental schedule for administrative and general offices. This schedule is intended for corporations, firms, or individuals operating more than one mine, quarry, or reduction works, with a central office for all of them. Upon this schedule should be reported the employees of such central office with their salaries or wages, and all other employees whose work is not confined to one particular mine, quarry, or reduction works, such as general superintendents, machinists, surveyors, etc. All general expenses are also to be reported on this schedule and the data relating to capital stock, bonds, dividends, and assessments of incorporated companies. No data reported on this schedule should appear on the separate reports for the individual mines, quarries, or reduction works. Separate schedules are supplied for these individual plants.

19. Special Schedule No. 6b, a supplemental schedule for bluestone, granite, limestone, marble, sandstone, slate, and trap rock quarries, upon which a full description of the quarrying and stone-dressing machines in use should be given. This schedule is to be filled out in addition to and supplementary to Special Schedule No. 6 for all stone quarries.

Geological Survey Schedules.

20. There are, in addition to the schedules of the Census Office, schedules of the Geological Survey, and upon these are to be reported in detail the statistics of production of the various minerals, with other information as indicated on each. They are enumerated as follows:

Slate.
Marble.
Trap rock.
Granite.
Sandstone.
Bluestone.
Limestone.
Sulphuric acid.
Barytes.
Mineral paints.
Mica.
Salt.
Phosphate rock.
Gypsum.
Emery and corundum.
Millstones.
Grindstones.
Soapstone and talc.
Bituminous coal.
Anthracite coal.
Coke.
Coke, by-product plants.
Brick and tile.
Pottery.
Clay mined.
Mineral waters.
Cement.
Deep mine (precious metals).
Reduction works at mines.
Placer and surface mines (precious metals).
Local or custom mills or smelting works (precious metals).
Natural gas.
Crude petroleum.
Iron ore.
Manganese ore.
Gas, tar, and ammonia.
Precious stones.
Minor minerals (a general schedule for the production of all other minerals not included in the foregoing list).

Industries Eliminated from Census Canvass.

21. Of the above minerals and subjects of inquiry by the Geological Survey it has been decided to eliminate from the Census inquiry the following: Brick and tile, coke, coke in by-product plants, gas, tar, and ammonia, mineral waters, pottery, salt, and sulphuric acid. Small placer gold mines at which less than two wage-earners are employed are also to be eliminated from the Census inquiry. Special agents are instructed not to obtain returns for these industries upon the Census schedule.

22. It is very essential that the Geological Survey and the Census Office schedules be transmitted together.

Mining and Manufacturing Industries.

23. There are several branches of mining in which the mineral products do not reach the market in the crude condition, but are subjected to certain processes at the mine or quarry before being regarded as marketable commodities. These may be processes of milling, separating, washing, burning, calcining, or other forms of manufacture. In some industries these processes are performed entirely at the mine or quarry, and in such cases the special agents are instructed that the census schedule should include the statistics of employees and wages, miscellaneous expenses, and supplies and materials involved in the entire work of mining the crude material and preparing the same for market. For example, the following branches of mining and quarrying are of this character: Emery and corundum mines, where finished emery wheels are frequently manufactured; mica mines, sheet and crushed mica being the finished product; graphite mines, where the crude graphite is refined; grindstone and millstone quarries, where grindstones and millstones are the finished products; mines or quarries of kaolin, flint, ocher, barytes, manganese, chalk, talc, mica, umber, sienna, and other iron-oxide colors, where the crude mineral is ground or otherwise prepared; marble, granite, and other stone quarries, where the stone is cut and dressed, and monuments and tombstones are manufactured; slate quarries, where roofing slate, slate blackboards, school slates, and sanitary plumbing slate slabs are manufactured. In all such cases as the foregoing and others where any form of manufacturing is necessary at the mine or quarry before the product is placed on the market the census schedule should cover the entire work of the establishment.

Instructions for Filling out Schedules.

24. The Census Office schedules must be carefully prepared in conformity with the general practice of the division of manufactures in gathering statistics concerning manufactures, street railways, electric light, etc. The agents who have been detailed from the Census Office are familiar with these methods. All questions must be carefully answered, and amounts reported in answer to each inquiry should be tested individually and with the totals. The following general instructions for filling out Special Schedule No. 6 will apply to the similar general features and inquiries of each of the several census schedules.

25. Give on the first page of the schedule the name of the mine or quarry; the character of the mineral; the name of the company, firm, or individual owner; the location of the mine or quarry (state, county, nearest city or town, and post office); and the address of the general office, if different from that of the mine or quarry. Obtain, also, the signature and official designation of the person furnishing the information. The signature of the special agent should be written on each schedule returned.

Inquiry 1.—Character of Organization.

26. Under this inquiry should be reported the character of the organization under which the mine or quarry is owned and operated.

Inquiry 2.—Capital Stock, Bonds, Dividends, and Assessments of Incorporated Companies.

27. This question does not apply to any other forms of mining and quarrying organizations than incorporated companies. Account

for the entire amount of common and preferred stock and bonds, respectively, authorized, the amount of each issued up to the end of the year for which the report was made, giving the number of each class, the par value, and the full amount of dividends paid during the year on each class of stock and on bonds. The total amount of assessments levied by organizations known as "assessment companies," whether incorporated or unincorporated, should also be reported.

INQUIRY 3.—EMPLOYEES, SALARIES, WAGES, ETC.

28. Account for all persons employed at the mine or quarry, both in the management and in the operation of the plant. Give the number of officers who receive salaries (not the number of stockholders), and the gross amount of their salaries. Report separately the number and wages of each class of employees specified. The salaries and wages should include board or rent furnished as part compensation.

29. The wages reported for miners or quarrymen and stonecutters should be their net wages, and should not include the cost of supplies furnished by the company and charged to them, such as explosives, lamp oil, etc., and blacksmithing charges.

30. Care should be taken that those employed "above ground" and those "below ground" be reported separately.

31. Amounts paid for contract work not done by employees hired directly, and the number employed in such work, must not be included in this inquiry, but be reported in answer to Inquiry 6.

32. The average number employed during the year is the number that would be required at continuous employment for the twelve months to produce the quantity of product reported. There should be no difficulty in securing this information for the plant of ordinary size, but it may be that the large companies keep an itemized pay roll, the total only being carried forward from each week or month. In such cases it will be necessary to add on a separate sheet the pay roll of each week or month for each class of employees.

33. *Average number of wage-earners at specified daily rates of pay.*—This inquiry is designed to ascertain the average number of employees for each of the eight classes enumerated that receive the daily rates of pay specified.

34. *Average number of wage-earners employed during each month.*—The object of this inquiry is to obtain the average number of wage-earners employed during each month as distinguished from the average number employed during the entire year. If properly answered, it shows the variation in the number employed at different seasons of the year.

INQUIRY 4.—METHOD OF PAYMENT FOR MINING OR QUARRYING.

35. This inquiry is intended to elicit information regarding the manner in which payment is made for mining or quarrying when not done by the day. It has an important bearing upon labor and wages in certain branches of the mining industry, particularly in coal mining, and should be very carefully answered. The manner of payment for the class of work referred to is sometimes different at the same mine. This should be reported if not done by the day, with the average number of men engaged and the total amount paid for such work, also any allowances that may be made in addition to the regular schedule of wages for difficult mining or other considerations.

INQUIRY 5.—TIME IN OPERATION.

36. The object of this inquiry is to ascertain the time that the mine or quarry was in operation during the year.

INQUIRY 6.—CONTRACT WORK.

37. Extensive improvements or development work, such as tunneling, shaft sinking, boring test holes, etc., are frequently let out by contract, and are not done by regular employees of the mine or quarry. The amount paid for such work, the average number of men engaged and the number of days employed, should be reported. Although the book accounts of such work, except the amount paid for it, are not kept by the mine operator, it is thought that a correct estimate of the average number of men engaged and the number of days employed can be furnished.

INQUIRY 7.—SUPPLIES AND MATERIALS.

38. The actual cost of all supplies and materials used during the year, including freight paid on the same, must be reported. The cost of the following materials should be reported under this inquiry: Lumber and timber used for repairs, mine supports, track ties, cars, and for all other purposes; iron and steel for blacksmithing, rails, frogs, sleepers, etc., for tracks and repairs, parts of machinery and tools used for renewals and repairs; explosives, water for boilers and for other purposes, fuel, illuminating and lubricating oils, machinery supplies, etc.

39. It is frequently the case when the crude mineral is put through a process of milling, refining, calcining, or other manufacturing at the mine or quarry, as at gypsum, limestone, and cement quarries, that crude material is purchased from other mines or quarries that are not equipped for such work. The quantity and cost of material so purchased should be separately reported under this inquiry.

INQUIRY 8.—MISCELLANEOUS EXPENSES.

40. All items of expense incident to the operation of the mine or quarry, not accounted for under Inquiries 3, 4, 6, and 7, must be reported under this inquiry. Care should be taken that royalties paid for mineral taken out from leased land and other forms of rent for the mine or quarry be reported separately under the first item of this inquiry. Under the second item should be reported all other miscellaneous expenses, such as taxes on real and personal property, insurance on buildings, interest on borrowed money, etc. Do not include any portion of the freight reported under Inquiry 7 as paid on supplies and materials.

INQUIRY 9.—PRODUCT.

41. As stated in a preceding paragraph, the statistics of production will be reported in detail on the schedules of the Geological Survey, and only the total quantity and total value will be reported on the Census schedule. The figures on both schedules must agree. The value reported should be the spot value f. o. b. at mine or quarry, except in the returns of natural gas wells, where the price to the consumer should be given, as obtained from the books of the company.

INQUIRY 10.—POWER.

42. Under this inquiry should be reported all mechanical power employed, either owned or rented, including the number and horsepower of all engines, motors, water wheels, etc., used for ventilating, pumping, hoisting, derricks, surface machinery, and all other purposes.

43. Care should be taken to report correctly "Power owned" and "Power rented." When an entire plant, including engine or water wheel, is rented, the power thus controlled is to be regarded as "Power owned" and entered under 10a. "Power supplied by other establishments" (10c) should include only cases where the mechanism generating the power is in the control of another party.

44. The foregoing instructions will apply to all inquiries in the Census schedules, except several special and additional inquiries peculiar to certain branches of the mining industry.

Instructions for answering those special inquiries are given in the following:

SPECIAL SCHEDULE NO. 8.—COAL MINES.

45. In addition to the detailed information relating to the product of coal mines provided for in the schedules of the Geological Survey, under Inquiry 9, on the Census schedule the number of cars of run of mine coal taken from the mine during the year, and the average capacity of the mine cars, in pounds, should be reported. This information is easily accessible, and can be given in all cases with little trouble by the foreman at the colliery.

46. The information called for in Inquiries 11, 12, 13, 14, and 15 relates to the equipment of the mine and can be readily given by the foreman. It is important that complete information be given in reply to these inquiries. The rate of royalty per ton should be given under Inquiry 16, if paid on all or part of the output of the mine during the year. The total amount so paid should be reported under Inquiry 8.

SPECIAL SCHEDULE NO. 9.—PETROLEUM AND NATURAL-GAS WELLS.

47. It is important that complete statistical information regarding the storage capacity for crude petroleum at the wells and the development and exploration work done during the year and the results of that work, as evidenced by the number and condition of wells drilled during the year, be reported in reply to Inquiries 10 and 11. Describe fully, also, the diminution of pressure, if any, that has occurred during the year.

SPECIAL SCHEDULE NO. 10.—GOLD, SILVER, LEAD, AND COPPER MINES.

Inquiry 2.

48. This inquiry should be answered in all cases when the working of a mine was discontinued for a number of years and subsequently resumed.

Inquiry 9.—Miscellaneous Expenses.

49. The four items of rent specified under this inquiry should be reported separately in case the owner of the mine and mineral lands, the party who erected the mining plant and developed the mine, and the operator are different persons, and the lessee is required to make separate payments to the patentee, to the development company, to the tunneling company, etc.

50. The answers should in all cases be obtained from the mine operator, but the addresses of the owner and lessor from whom the operator holds his lease should be obtained for reference, likewise the address of the tunneling company.

51. In case the mine is worked by the hydraulic method, the address of the owner of the water plant should also be obtained for reference.

52. If, in addition to the four items of rent, offices or any other facilities are rented, specify each kind and state the total amount paid in the column reserved for the same.

53. If two or more items of rent are paid in one sum to the same party, give the amount paid and state for what it is paid.

Inquiry 10.—Product.

Gross value of metallic contents, as reported to the United States Geological Survey.

Deductions: Charges for treatment and freight, per ton and total.

Net value of mining product.

54. The gross value of the metallic contents of the product is to be transferred to this schedule from the schedules of the United States Geological Survey. In order properly to answer this inquiry, it must therefore be read in conjunction with the schedules of the Geological Survey; there is one schedule relating to "Deep mines" and another relating to "Placer and surface mines."

55. *Deep mines.*—The product of deep mines is ore. Ore is either sold, treated at a mill connected with the mine, or treated at a custom mill.

56. The customary method of settlement for ore purchased by samplers, smelters, etc., is the following: The ores are sampled and the contents of each metal are determined by assay. All the gold contained in the ore is paid for at a stated rate, usually very near the rate paid by the United States mints or assay offices for unrefined bullion—that is, about $20 per ounce fine. The silver contents are paid for at the current New York price per ounce fine, with a discount of a few per cent for losses in smelting, etc. Base metals contained in the ore are paid for at a stated price per unit (per pound, or percentage contained in the ore).

57. From the gross value of the metallic contents thus computed deduction is made for working costs and freight at a stated rate per ton of ore. The balance, after making these deductions, is the net value of the ore f. o. b. at mine, for which payment is made by the purchaser.

58. The Geological Survey schedule for "Deep mines" contains the following inquiry:

"4. Total bullion contents of above ore sold or treated in 1902."

59. If the ore was sold, the special agent, after entering on the Geological Survey schedule for "Deep mines" the quantities and *gross* values of the precious and base metals contained in the ore, will transfer the "Total value" from that schedule to Special Schedule No. 10, entering it in the blank space against "Gross value of metallic contents, as reported to the United States Geological Survey."

60. Next enter under "Deductions" the charges for treatment, per ton and total, and freight, per ton and total. Unless the rates per ton underwent a change during the year 1902, the total must be equal to the rate per ton multiplied by the total amount of ore sold in 1902, reported in answer to Inquiry 2 on the schedule of the Geological Survey.

61. The "Net value of mining product" is equal to the total amount realized by the mining company for all ores sold during the year 1902. The amount should be furnished by the manager of the mine. It must be equal to the gross value reported to the Geological Survey less charges for treatment and freight reported under this inquiry. If the balance does not agree with the answer, the discrepancy will indicate that some of the answers are incomplete or incorrect. The mistake should be corrected before leaving the establishment.

62. If the ore is treated at a mill operated under the same management, a report similar to the foregoing should be made whenever separate accounts are kept for the mine and the mill. If this is not possible this inquiry need not be answered, and an answer will be given, covering both the mine and the mill, on Special Schedule No. 11, under Inquiry 9.

63. If the ore is treated at a custom mill and the bullion, concentrates, or other product, after being returned to the mine operator, are sold to a smelter, the total charges for treatment should be reported, including both the cost of milling and the smelting charges; the freight should in such case likewise include both the cost of carriage to the custom mill and the freight charges made by the smelter.

64. *Placer and surface mines.*—Most of the placer gold finds its way into the United States mints and assay offices, and is paid for according to weight and fineness at the legal rate, a small charge being made for refining. The crude gold or dust which goes to private smelters and refineries is paid for at a fixed rate per crude ounce for every producing district. Accordingly, if the gold dust is deposited at a United States mint or assay office, the value on the schedule of the United States Geological Survey should be given at the full legal rate of $20.67 per ounce fine, and the mint charges should be entered on Special Schedule No. 10, under "Deductions, charges for treatment."

65. If any values are obtained from tailings, the same should be added to the value of the gold product, and the total should be transferred to Special Schedule No. 10.

66. If the gold dust is sold to a private smelter, the value given will be that fixed per ounce crude, as explained above; the special agent, after transferring the same from the schedule of the Geological Survey to this schedule, should write in the blank spaces under "Deductions" the word "None"; the gross value of metallic contents transferred from the schedule of the Geological Survey should be repeated in the blank space reserved for "Net value of mining product."

INQUIRY 11.—NAME AND ADDRESS OF MILL OR WORKS AT WHICH THE ORE IS TREATED.

67. If the mill at which the ore is treated is operated by the same mining company, state the fact in answer to this inquiry.

68. If the ore is treated at a custom mill, state "Treated at a custom mill," and give the name and address of the same.

69. If the ore is sold, state "Sold to (giving name and address of buyer)."

70. If it is deposited at a United States mint or assay office, state at which.

71. *By what method is the ore conveyed from the mine to the mill?* The method should be described only when the mill is located in the vicinity of the mine, for example: By wagon, by tram, by steam or electric railroad connecting the mine with the mill, etc. If the ore is shipped by freight or express, state the fact.

INQUIRY 12.—MINERAL LANDS.

72. This inquiry is intended only for "Mineral lands" which are held under a patent from the United States Land Office, or under a location certificate, and not for any other real estate.

INQUIRY 13.—WATER PLANT.

73. This inquiry relates only to hydraulic mines, or such as were formerly worked by the hydraulic method and have since turned their water plant into a source of motive power.

INQUIRY 14.—LENGTH OF RAILROAD TRACKS OWNED.

74. All tracks should be reported; those owned by the mining company itself, or by a railroad company whose stock is held by the mining company. State separately the length of tracks on the surface and underground. If no tracks are owned, answer "None."

INQUIRY 16.—MACHINERY.

75. State number of machines of each class and kind of power by which they are operated. Do not give horsepower, which must be reported under Inquiry 15.

SPECIAL SCHEDULE NO. 11.—REDUCTION WORKS (OTHER THAN SMELTERS).

76. A separate report must be made on this schedule for every reduction works, whether operated independently or jointly with a mine. In case, however, no separate accounts are kept for the mine and the works, a full report covering both should be made on Special Schedule No. 10, leaving Inquiry 10 on that schedule unanswered, and answers should also be given to Inquiries 4, 5, 9, 10, and 12 on this schedule.

INQUIRY 5.

77. This inquiry should be answered only where the product of the reduction works is shipped for further treatment to some other custom mill (for example, where concentrates are treated at a cyaniding mill), or where the product of the mill is treated at a custom smelter.

INQUIRY 6.—MATERIALS.

78. *State character of materials used, whether ore, tailings, or other materials.*—The answer should enumerate all materials, those coming from the company's own mines as well as those bought or treated for customers.

79. *Total assay contents and value of all materials bought in 1902.*—The answer to this inquiry should be confined to such materials only as were bought from other persons.

The method of settlement for purchased ores is fully described in the instructions to Special Schedule No. 10, Inquiry 10, to which reference is here made.

INQUIRY 9.—PRODUCT.

80. *Gross value of metallic contents as reported to the Geological Survey.*—The answer to this inquiry must be transferred from the schedule of the Geological Survey relating to "Reduction works at mines," or from that relating to "Local or custom mills or smelting works," as the case may be. It should be remembered, however, that Special Schedule No. 11 applies only to "Reduction works other than smelters." Special schedules relating to smelters will be placed in the hands of special agents in particular cases only.

81. In order that the information wanted by this office be properly transferred from the schedules of the Geological Survey, the following instructions should be carefully noted. The method of settlement for concentrates, amalgam, cyanides, crude bullion, etc., is similar to that described in the instructions to Special Schedule No. 10, Inquiry 10, to which reference is made.

82. *Reduction works at mines.*—In this case the product will be reported on the following four schedules: (1) Schedule of the Geological Survey relating to "Deep mines." (2) Schedule of the Geological Survey relating to "Reduction works at mines." (3) Census Schedule No. 10. (4) Census Schedule No. 11.

83. If, in addition to the ores mined and milled by the same company a part of the product of the reduction works is from purchased ores, then the bullion contents, reported on the first of the above-enumerated schedules, will give only the product of the company's own mines, and the bullion contents reported on the second schedule the whole product of the reduction works. The former should be transferred to Special Schedule No. 10, and the latter to Special Schedule No. 11.

84. *Custom material.*—What has been said in reference to purchased ores likewise applies in the event, in addition to the ores mined by the same company, custom ores were treated by the reduction works. In many cases, however, the management of the reduction works has no information as to the metallic contents of custom ores treated, beyond their tonnage. Whenever custom ores were among the materials treated at the reduction works, the special agent should ascertain whether the bullion contents of the same are or are not included in the amounts and values given in the schedule for "Reduction works at mines;" and in transferring the value to Special Schedule No. 11, Inquiry 9, he should write immediately after "Product" the following words: "including product of custom ores," or "not including product of custom ores," as the case may be.

85. *Geological Survey schedule relating to "local or custom mills or smelting works."*—As stated above, reports from smelters are not to be transferred to Special Schedule No. 11. The instructions given above in relation to "Custom materials" likewise apply to mills not connected with mines.

INQUIRY 10.—CUSTOM WORK DONE BY THIS ESTABLISHMENT.

86. Report separately the quantity treated of (1) ore, (2) concentrates or other material previously treated at other reduction works, (3) tailings; state the total amount received for the treatment of each, exclusive of freight, and the total freight paid on each.

INQUIRY 12.

87. Give the addresses and character of establishments to which the products were sold or shipped for treatment, for example: Gold, to the United States mint at (location); silver, to the smelter of (name) at (location); concentrates from tailings, to cyaniding plant of (name) at (location), etc.

SPECIAL SCHEDULE NO. 6a, ADMINISTRATIVE AND GENERAL OFFICES.

88. As previously explained, this schedule is intended for the general office reports of establishments operating more than one plant. In such cases great care should be taken that no data included in this schedule be included in any of the reports for the individual mines or quarries, and all data chargeable to a particular mine or quarry should be included in the report of that plant and not in the administrative or general office report.

SPECIAL SCHEDULE NO. 6b, STONE QUARRIES.

89. This schedule is supplemental to Special Schedule No. 6, for the reports of stone quarries, and should in all cases be returned with the complete report of stone quarries. It should contain a full description, as provided on the blank, of all quarrying and stone-dressing machines in use. If such machines are not used, Special Schedule No. 6b should be returned containing a statement to that effect.

---

90. In order to insure the success of the cooperation between the Geological Survey and the Census Office, in taking the census of mines and quarries, there must be perfect agreement between the published reports of the two bureaus. To secure this, and to minimize the work of correspondence, correction, and revision, the utmost pains should be taken to obtain, for all branches of the investigation, correct returns in which the answers to the various inquiries will conform to each other and harmonize throughout. Careful study should be given to all instructions relating to the work of the special agents.

APPENDIX C.

INSTRUCTIONS FOR EDITING AND REVISING THE SCHEDULES.

GENERAL INSTRUCTIONS.

All corrections or additions to schedules should be made neatly and plainly in red ink.

No change or correction of importance should be made except on the advice of the clerk in charge.

Whenever cents are reported on a schedule, if 50 cents or over, a dollar should be added to the amount and the cents striken out; if less than 50 cents, they should be stricken off the schedule.

The Instructions to Special Agents giving directions for filling out the schedules should be carefully studied in so far as they affect the census schedules. As shown therein each mineral should be reported upon a specified schedule. This question should receive primary consideration. The instructions relating to the various industries to be reported on the several schedules are as follows:

Reports should be secured for all mines and quarries and for reduction works engaged in reducing and concentrating the ores of the precious metals. The schedules on which these reports are to be made are seven in number: Special Schedule No. 6, for mines and quarries in general, for which no other special schedule is provided. Mines and quarries of the following minerals are to be reported on this schedule: Slate, marble, trap rock, granite, sandstone, bluestone, limestone, barytes, mineral paints, mica, phosphate rock, gypsum, emery and corundum, millstones, grindstones, soapstone and talc, clay, cement rock, iron ore, manganese ore. Special attention is called to the fact that on this schedule, also (Special Schedule No. 6), should be reported the nonargentiferous or soft-lead mines located east of the Rocky mountains, the copper mines of the Lake Superior region, and zinc mines. Other minerals, mined as such, to be reported on this schedule, except where they accompany minerals of more importance, as platinum in gold placers, are the following: Antimony, asbestos, asphaltum, borax, bauxite, chrome ore, cobalt, feldspar, fibrous talc, flint, fluorspar, fuller's earth, garnet, graphite, infusorial earth and tripoli, magnesite, marls, molybdenum, monazite, oilstones, platinum, precious stones, pyrite, crystalline quartz, quicksilver, rutile, sulphur, tungsten, uranium, and vanadium. Special Schedule No. 8, for coal mines, both anthracite and bituminous, and anthracite coal washeries. Special Schedule No. 9, for petroleum and natural-gas wells. Special Schedule No. 10, for gold and silver, and argentiferous and auriferous lead and copper mines. Special Schedule No. 11, for reduction works of the precious metals (other than smelters and refineries). Special Schedule No. 6a, a supplemental schedule for administrative and general offices. This schedule is intended for corporations, firms, or individuals operating more than one mine, quarry, or reduction works, with a central office for all of them. Upon this schedule should be reported the employees of such central offices, with their salaries or wages, and all other employees whose work is not confined to one particular mine, quarry, or reduction works, such as general superintendents, machinists, surveyors, etc. All general expenses are also to be reported on this schedule and the data relating to capital stock, bonds, dividends, and assessments of incorporated companies. No data reported on this schedule should appear on separate reports for the individual mines, quarries, or reduction works. Separate schedules are supplied for these individual plants. Special Schedule No. 6b, a supplemental schedule for sandstone, granite, marble, trap rock, bluestone, limestone, and slate quarries, upon which a full description of the quarrying and stone-dressing machines in use should be given. This schedule is to be filled out in addition to and supplementary to Special Schedule No. 6 for all stone quarries.

CLASSIFICATION.

The schedules may be separated into three main groups—those representing establishments that were active and engaged in production during 1902, idle or nonproductive establishments, and schedules that in no manner represent active or idle mines or quarries but are from men who have retired permanently from business, from mines or quarries that have been worked out or abandoned, or from establishments that may be eliminated from the Census of Mines and Quarries, or for other reasons. Reports from mines or quarries that were in process of development—no production being reported during 1902—should be classified as "Idle" unless there are special reasons for omitting them presented in the information accompanying the schedule. These three classes of schedules should be filed separately and the two latter should be stamped "Idle" or "Omit," respectively, on the right of the center of the top margin of the schedule.

Each schedule should be classified with the name of the mineral of chief importance produced, as reported on the production card of the Geological Survey, the classification to be written in red ink on the upper left-hand margin of the schedule. The number placed on the upper left-hand corner of the schedule, which corresponds to the number on the schedule of the Geological Survey, should not be obliterated or in any manner obscured in writing the classification.

It sometimes occurs that two classes of mineral, or two products which require different classifications, are produced in the same quarry, and only one report has been made covering the entire operations. In such cases it is frequently impossible to make any separation of the data reported under the several inquiries so as to present a separate report for each branch of the business. Instances of this kind are when limestone quarrying and cement manufacturing are done at a quarry and a part of the product of the quarry is sold in its crude state for building and other purposes, or when grindstones are made at a sandstone quarry and a certain proportion of the quarried stone is sold for building and other purposes, this condition in both of these instances necessitating two reports of the product to the Geological Survey.

It is impossible or impracticable in such cases to make a report for each branch of the business, therefore the combined report will be accepted and should receive the classification of the predominating products as shown by the production slips. A Census schedule should be made out for the less important product, con-

taining only such information as is necessary for filing purposes, such as the classification, name, and location, but no statistical data except the product. This schedule should be made out in red ink. Cross references should be made in each schedule and Survey slip, one to the other. In the Census schedule which contains the complete report the cross reference should be about as follows: "See also Cement No. 86, Jones and Smith, Pageville, Ohio, for additional cement product." On the blank Census schedule for the less important product the cross reference should be in about the following terms: "See also Limestone No. 72, Jones and Smith, Pageville, Ohio, for all data other than cement product." Corresponding references should be written on the Survey slips.

The following instructions are intended to apply to Special Schedule No. 6 and to the similar general features and inquiries of the other Census schedules:

The classification should be verified by comparing with the copy of the Geological Survey schedule which accompanies each Census schedule. The schedule should receive close examination to ascertain if it includes more than one mine or quarry, and if so, that fact should be clearly stated in red ink in the space below the classification at the top of the schedule on the left-hand side as follows: 3 mines or 5 quarries, as the case may be.

Title page.—The information called for on the first page of the schedule should be reported in full, each item of information being written plainly in the space provided.

Inquiry 1—Character of organization.—It is probable that the character of the organization under which mines and quarries are operated will be in all cases one of the five classes specified. This information should appear on all schedules.

Inquiry 2—Capital stock, etc.—If the character of organization as reported under Inquiry 1 is that of an "incorporated company," the necessary information relating to the same should appear under this inquiry. The number of shares of each kind of stock and the number of bonds, with the total par value of the same, should be reported. The total par value should be that of the entire amount of bonds or stock, and not that of a single share. It is not necessary that all incorporated companies report bonds and both classes of stock. Bonds and preferred stock will very frequently not appear, as this class of liabilities in the cases of many corporations is solely common stock.

The amount reported as issued should not be in excess of the amount reported as authorized, and the number of shares of stock and the number of bonds should not be inconsistent with the par value.

The "authorized" and "issued" stock should be reported in all instances.

The amount of dividends, if any, paid during the year on common and preferred stock should be the result obtained by multiplying the par value of common and preferred stock issued to the end of the year by the "rate" reported. If the amount is reported and no rate, the rate should be calculated and supplied, and vice versa.

A report showing bonds should show the rate of interest on the same, although no interest is reported as paid.

In cases where an incorporated company owns more than one mine or quarry and a Special Schedule No. 6a has or has not been filled out, it frequently occurs that the details of capital stock and the general officers are included in each of the individual schedules, thus duplicating and triplicating, etc., this information. In all cases of this kind, after being assured that an apportionment of the capital stock, etc., has not been made among the individual schedules, the duplicated data should be stricken off all schedules except one and a note substituted to the effect that the information is reported on Schedule —— (giving the name of the mine and location).

Inquiry 3—Persons employed.—The information reported under this inquiry should be very carefully examined, and the three sections of the inquiry should agree with each other and with other inquiries that have the least bearing upon the question of employees and wages.

The numbers of the several classes of employees reported should not be out of proportion with each other, nor with the character and extent of the mine or quarry reported on the schedule. No employees should be reported "below ground" for quarries or surface mines.

The average number of "wage-earners," which includes all classes of employees other than general officers, superintendents, managers, etc., and clerks reported in the first section of the inquiry, should agree in number with those reported under "Wage-earners at specified daily rates." The total average number of wage-earners under these two sections of the inquiry should accordingly be written in the margin of the schedule. The total wages reported for all employees after clerks, except foremen "below ground" is the amount of wages to be used in comparison with the second section of the inquiry. This amount should be written in red ink in the margin of the schedule. The wages that would be earned by the employees reported at specified daily rates, at the rates given, the mean rate being used in the calculation, and for the time in operation as reported under Inquiry 5, should agree approximately with the amount reported under the first section of the inquiry. This comparison should be made for the entire number of wage-earners and for each corresponding class of wage-earners. To obtain the average number of wage-earners during the year, reported under "Average number of wage-earners employed during each month," add the numbers reported for each month and divide the total by 12, the number of months in the year. This calculation should be made on the left-hand margin of the schedule in red ink.

The average number employed during the year, under the first and second sections of Inquiry 3, must be the number that would be required to produce the quantity of product reported, working continuously for twelve months. Therefore, if a mine or quarry had suspended operations for any protracted length of time during the year, the average number of wage-earners, under the first and second sections of Inquiry 3, must be reduced by that proportion of the number reported that the period of idleness is to twelve months, providing the average number as reported in answer to these sections is approximately the same as the average number employed during each month the mine or quarry was in operation. When necessary to make such reduction, the amounts paid in wages to the several classes of employees must be approximately the amounts they would receive if employed the full number of working days in the year at the specified daily rates of pay, and not the amounts they would receive for the actual number of days employed at the rates reported. The reduction of the average number of employees that may be necessary should not always be applied to "Superintendents, managers, etc.," "Clerks," and "Engineers, firemen, etc.," as these employees generally work full time whether the mine is idle or in operation. However, if the computation shows that they were employed only while the mine was operated, the reduction should be applied to them the same as to the other employees.

There should be a substantial agreement in the rates of wages shown on the different schedules from establishments engaged in the same branch of industry in the same locality.

Inquiry 4.—The information reported under this inquiry should be reported also under Inquiry 3. The number of employees and amount paid should be included in Inquiry 3, under "Miners or quarrymen and stonecutters" for surface mines or quarries, and under "Miners" and "Miners' helpers" for underground mining. The inquiry is intended to develop the manner of payment for the actual work of mining or quarrying when not done by the day. As there is not frequently a diversity in the method of payment for identical work in the same mine or quarry, it is thought that the data reported as to the average number of employees and total

amount paid in this inquiry will, in most cases, be the same as that reported under the heads provided for this information in Inquiry 3.

Inquiry 5—Time in operation.—The information reported under this inquiry should be considered in connection with the answers to Inquiries 3 and 9, and in verifying the amount reported as paid in wages by the specified daily rates and the number of wage-earners reported at each, the number of days in operation, and the number of shifts of workmen reported under this inquiry should be taken into account. The number of shifts of workmen reported will be one in the large majority of cases, and sometimes two or three. A larger number of shifts is open to question. In quarrying and surface mining if more than one shift is reported it is questionable. This is also true of certain other branches of mining. The number of hours to a shift will in most cases be 10, frequently 8, and sometimes 12.

Inquiry 6—Contract work.—The information reported under this inquiry is entirely separate from any data given under Inquiry 3 and should not be included therein. It is frequently the custom to let such work as tunneling, shaft sinking, boring, etc., out by contract, and no record is kept by the officers of the mine or quarry of the wage-earners employed and the wages paid, and as it is in most cases impossible to obtain the information from the contractor, it will be estimated and given by the mine or quarry operator. Contract miners or quarrymen who work by the ton, car, yard, etc., should not be reported under this inquiry but under Inquiries 3 and 4.

Inquiry 7—Supplies and materials.—The character of the expenditures to be reported under this inquiry is shown on the schedule. It should always be considered in connection and compared with the product reported and answers to other inquiries. Except under extraordinary circumstances, the amount reported will not be in proportion to the value of the product. It will frequently be found to be the case that no amount is reported under this head, particularly in very small mines or quarries, and in such cases it should be accepted as correct.

It is frequently the case when the crude mineral is put through a process of milling, refining, calcining, or other manufacturing at the mine or quarry, as gypsum, limestone, and cement quarries, that crude material is purchased from other mines or quarries that are not equipped for such work. The quantity and cost of material so purchased should be separately reported under this inquiry.

Inquiry 8—Miscellaneous expenses.—All items of expense incident to the operation of the mine or quarry, not accounted for under Inquiries 3, 4, 6, and 7 must be reported under this inquiry. Care should be taken that the royalties for mineral taken out from leased land and other forms of rent for the mine or quarry be reported separately under the first item of this inquiry. It will be frequently found to be the case that no amount is reported under this head, particularly in very small mines or quarries, and in such cases it should be accepted as correct.

Inquiry 9—Product.—Inclosed with each schedule will be found a copy of the card of the Geological Survey containing a detailed report of the product. The product as reported on this card, and not as entered on the schedule, will be tabulated and included in the published reports. It will, therefore, be taken as the product in editing the schedules when considering its relation to the data reported in reply to the other inquiries.

This question should receive very careful examination and be carefully compared with the replies to other inquiries. The quantity reported should be consistent with the number of employees and the time in operation; the kind of mineral, and the conditions of mining it should also be considered in this connection. The value per unit of the product should be examined to see that there is not a very great difference between the average value shown in the schedule and the average ruling price of the article under consideration during 1902.

As it is necessary that the quantity and value of the product published in the reports of the Census Office and in those of the Geological Survey agree, under no circumstances should any change be made in this information without the permission of the section chief.

Inquiry 10—Power.—The first consideration in examining this question is as to whether or not the use of mechanical power is required. This question is determined by the size of the mine or quarry, and by the character or method of mining. In a very large number of quarries and open mines generally, no power is used, but if they are of considerable magnitude some equipment for power purposes is necessary. In a large majority of cases the power reported will be steampower.

Before closing any branch of the mineral industry, and tabulating the schedules, the files should be searched and all No. 6a schedules withdrawn. The information reported under Inquiry 6 should then be carefully checked against the individual mine and quarry schedules to see that all the schedules are on file.

If the mines or quarries are all located in the same county, the data reported on the No. 6a schedule should be added to any one of the individual schedules and an examination made of the others, for the purpose of eliminating this data, if duplicated on such schedules. Care should be taken that all information under Inquiries 1 and 2 be stricken off all schedules, except one, and a suitable cross reference made to the schedule containing the information. If the mines or quarries are located in different states or counties, or if there is more than one branch of mining, the data on the No. 6a schedule should be apportioned among the different states and counties, or branches of mining, as the case may be, the apportionment being based on the value of the product.

INSTRUCTIONS FOR EDITING SPECIAL SCHEDULES.

The foregoing instructions are intended for general application in editing the returns of mines and quarries of all kinds. In addition, there are certain special schedules which contain peculiar features and require further explanation.

Special Schedule No. 8—Coal Mines.

Inquiry 3—Persons employed.—Care should be taken that the employees are correctly reported "above ground" and "below ground." Only an insignificant proportion of coal mines are surface mines, and in such cases the mines should be reported under Inquiry 14 as "Open cutting or stripping." Roughly stated, in bituminous coal mining, about nine-tenths of the entire force of employees work underground, but in anthracite mining, on account of the large plants on the surface for screening and cleaning the coal, the proportion underground is less than in soft coal mines, being about two-thirds.

The timbermen and track layers separately stated under the second section of this inquiry should be included among "All other employees" below ground, in the first section of the inquiry.

Inquiry 4—Average number of employees and rates paid.—As the actual work of coal mining is seldom done by the day, the number of miners and miners' helpers, with their earnings, should be reported here. This information should also be reported under the first section of Inquiry 3. Under the second section of Inquiry 3, where miners are paid by the ton, car, or yard, the specified daily rate under which those contract miners are reported should be the same for the entire number of this class of workmen. This rate should be estimated by the examiner from the total number of days in operation and total amount of wages paid, and should be the average daily earnings for the period that they are employed.

The "Total amount paid for such work" should agree with the amount reported as paid to miners and miners' helpers under Inquiry 3, and this amount should include the amount reported as paid for yardage or other allowances. As reported on this schedule, these allowances are frequently not included in the amount paid for mining. This may be verified by calculating the amount that would be received on the product reported, under Inquiry 9, at the

rate given under Inquiry 4, and if it is found that the amount is not included it should be added, the correction being made in red ink.

Inquiry 6—Contract work.—Care should be taken that the information given under this inquiry is not duplicated under Inquiries 3 and 4. It is probable that in only a small proportion of the schedules will information be given under this question, but, when reported, it should be treated as separate information not included under any of the other inquiries. In calculating the expense of operating the mine for the purpose of comparison with the value of the product, the amount reported as paid for contract work should be added to the other expenses for wages, supplies and materials, and miscellaneous expenses. When an amount is reported as paid, the "Average number of men employed" and the "Number of days" should also be reported.

Inquiry 8—Royalty and rent of mine.—In examining this inquiry, reference should also be made to Inquiry 16, and if any rate is given, an amount should be reported under Inquiry 8 as paid for royalties. This amount need not necessarily be the amount obtained from calculating the royalty on the number of tons reported mined under Inquiry 9, by the rate given under Inquiry 16. It can in no case be more, but may be less. Royalty is frequently paid on only a part of the product of the mine. It should be borne in mind that while the product is reported under Inquiry 9 in short tons, royalty is frequently paid in long tons. This is also true of Inquiry 4, the miners being paid for long tons and the product marketed in short tons. The general instructions apply to other features of Inquiry 8.

Inquiry 9—Product.—The data reported under this inquiry should not be inconsistent with information given under the other questions on the schedule. In bituminous coal mining the quantity of coal taken from the mine will agree in most cases with the marketable coal reported. If no information is given as to the number of cars of coal taken from the mine and the average capacity of such cars, the information should be supplied on the basis of the information given in other reports of mines in the same locality.

There will sometimes be a difference shown in the reports of bituminous coal mines between the quantity of coal hoisted and the quantity of marketable coal. In anthracite coal mining, owing to the larger proportion of coal which can not be utilized, the difference between the coal taken from the mine and that marketed will in many cases be considerable, the latter being less than the former. This is the result of the crushing, screening, and cleaning processes by which the coal is prepared for shipment.

Inquiry 10—Power.—In all large mines power in some form should be shown. The purposes for which it is required are for operating the crushing and screening machinery, for hoisting, pumping, and ventilating, and sometimes for other subsidiary purposes. A knowledge of the conditions found at coal mines is generally necessary to properly edit this question. If the opening to a vein is a shaft or slope, a hoisting engine will be required and in all probability one or more pumping engines, and if fan ventilation is employed, an engine will be necessary to operate the fan. Other methods of ventilation do not require the use of power.

Inquiry 11—System of haulage.—The information required under this inquiry is where a mechanical system of haulage has supplanted to some extent the use of animal power, such as horses and mules. It does not apply to the mechanical power used for hoisting coal from a shaft or slope.

Inquiry 12—Slate pickers or coal cleaners.—This inquiry is intended to apply only to anthracite mines. In separating the slate from the coal mechanical means have been substituted to a very large extent for boys, and the object of the inquiry is to determine the magnitude of this change or improvement in anthracite mining.

Inquiry 13—Washeries.—This question also is intended to apply only to anthracite coal mines. The use of washeries for cleaning coal, which formerly was allowed to lie on waste dumps, is comparatively a recent development, and by the use of such washeries a much larger proportion of the coal mined is available for shipment. Wherever a washery is reported under this inquiry there should be a separate report in the files giving the operations of the washery.

Inquiry 14—Openings to the works.—Whenever a shaft, slope, or tunnel is given as the nature of the opening to the vein, its depth or length in feet should be given. This information is not required where the mining is by drift or open cutting or stripping.

Inquiry 16—Coal mined on royalty.—If any rate is reported under this question, corresponding information should also be reported under the first item of Inquiry 8.

* * * * *

Special attention should be paid to the reports of bituminous coal mines where coke is manufactured. This information will be found on the slip containing the Geological Survey details of production. Only the capital stock, general officers, expenses, etc., pertaining to coal mining should be included in the schedule. If any of these data pertaining to coke manufacture are included, a separation should be made, based on the relative proportions of the two branches of the business.

GOLD, SILVER, LEAD, AND COPPER MINES.

In editing Special Schedules Nos. 10, 10a, 10b, 11, 11a, and 11b, the following instructions are to be followed and applied to the revision of the special features of the schedules, in addition to the application of the general instructions heretofore given to those inquiries which are identical in form in all the census schedules.

I. General Rules.

1. *By whom the report should be made.*

The report should always be made by the party operating the mine; when a mine is leased, one report should be obtained from the lessee and another from the owner, and both schedules should be combined; one should be marked "Owner's report," the other "Lessee's report." The owner should, in such cases, report only his own production and expenditures exclusive of the production of the lessees. An exception from this rule is made in the case of "leasers" or "tributers," of which see further.

In some cases one report is made indiscriminately combining the capitalization and some of the expenses of the owner with those of the lessee. In such cases a segregation should be made at this office; all items pertaining to the owner should be transferred to a separate schedule.

If a mine has changed hands in the course of the year 1902 separate reports are required from each owner or lessee for the time he operated. These reports should be combined, but all repetitions should be eliminated from one of the schedules. (See Inquiries 13, 14, 15, and 16.)

2. *Small and Chinese mines.*

There are a number of schedules marked "Small and Chinese" with nothing but an estimated value of the product. All such schedules should be assorted into a separate group to be tabulated on a separate sheet.

3. *General office.*

The address of the general office must be given on the title page of the Census schedule and also on the United States Geological Survey transfer slip (Schedules Nos. 10a and 10b). Very frequently the address is given on the United States Geological Survey transfer slip alone; in such cases it should likewise be written on the title page of the Census schedule.

If no general office is maintained separately from the mine, write in red ink after the words "general office" the word "mine."

4.—*Preliminary classification.*

All Schedules No. 10 should be classified under one of the following four groups:

First. Productive.

Second. Development work.

Third. Assessment work.

Fourth. Idle.

(1) A productive mine is one which produces ore or metal.

(2) If no ore or bullion is produced or the quantity is out of all proportion to the total amount invested in labor, the mine is classed under the second subdivision (development work).

(3) If a little work is done to comply with the requirements of the law, the mine is classed under the third subdivision (assessment work).

(4) If no work of any description was done during the year 1902, though some ore previously mined may have been shipped, the mine is classed under subdivision 4 as "idle."

In assorting schedules for tabulation those showing only development work without any production whatsoever must be segregated from those where production is reported as incidental to development.

Only schedules of the first and the second class must be edited; those of the third and fourth class require no editing.

All schedules relating to productive mines are to be assorted into two groups, viz, (1) placers and (2) deep mines. In editing the schedules these designations must be written in red ink on the title page of each schedule in the blank space after the words "Character of ore." The character of the mine is to be determined from the annexed Geological Survey schedule attached to Schedule No. 10. A deep mine is reported on Schedule No. 10a, a placer on Schedule No. 10b.

"Deep mines" are further assorted into two groups, *with or without a mill connection.* When a mine has no reduction works, the report is on Schedules Nos. 10 and 10a. Where a mine is connected with a reduction works, there must be Schedules Nos. 10 and 10a, 11 and 11a. These again are to be assorted into two subdivisions: Those where complete reports are furnished for the mine and the mill and those where the mine and reduction works are covered by one combined report, in accordance with the note on the title page of Schedule No. 10.

Placer mines as a rule require no mill; in some cases, however, where the ground is cement, it must be crushed in a stamp mill. In such cases a Schedule No. 11 is attached to Schedule No. 10, as in the case of a deep mine. Such reports must be segregated into a separate group. Reduction works without a mine connection are reported on Schedules Nos. 11 and 11a, except those running on old tailings, of which see further.

II. Mines Without Mill Connection.

1. *Development work without production.*

Where a report shows only development work without production, Schedule No. 10 alone is to be edited and prepared for tabulation; Schedules Nos. 10a and 10b should be disregarded.

Inquiry 9.—The total value of development work must in such cases be equal to the total amount expended and need not be reported separately. If it is so reported it should be erased. Very frequently the amount reported under this inquiry is equal either to the total wages and salaries or to the total wages alone, or to the sum of wages, salaries, and supplies, or to the sum of wages and supplies, or to the amount paid for contract work. All such answers should be erased. If, however, the amount reported is either in excess or short of any of these quantities, the schedule should be criticised; in the former case it may eventually disclose an omission under Inquiries 4, 7, or 8, or the amount may represent the expenditure of more than one year. Among the schedules of this class a number will be found where nothing but the amount expended in development work is reported; they probably represent merely assessment work on more than one mining claim in each case. All such schedules should be segregated into a separate group.

In many cases the work was done by the owner and his family and the amount reported is an estimate of the value of his labor. Such schedules should likewise be segregated into a separate group. (See further instructions to Inquiry 4.)

If the value of the development work done in such cases is estimated, write in the blank space, after "Amount expended in development work," the words "Done by owners."

In case development work is done in consideration of a lease and the amount is estimated, write similarly, "Done by lessees."

Aside from these instructions all schedules of this class are to be edited in accordance with the general rules applying to the Mining Census.

2. *Productive mines.*

The following instructions apply to all schedules where production is reported, including those where production is incidental to development work:

Inquiry 4.—In case the mine is worked by the owner or operator, with the assistance of members of his family, without hired labor, the fact should be noted as follows: Write in red ink after the words "persons employed," the words "no hired labor," erase the words "general officers" and write "owners working," giving the number, if known, in the first column. The same entry with regard to "owners working" should likewise be made where hired labor is employed, in addition to the owner's labor. By "owner" is meant the party in actual possession of the mine, whether as owner or lessee. The words "no hired labor" and "owners working" should also be written in red ink on the title page at the upper end of the right margin. All such schedules should be assorted into two separate groups.

Inquiry 5—Lessees.—In case the mine is worked under the so-called "leasing" or "tribute" system, i. e., when it is leased in blocks to a number of miners, each paying a royalty to the owner, no answers are required under Inquiry 4, but a report must be made under Inquiry 5, as follows:

After the words "If mining is paid for by the ton, car, or other unit, give the rate paid and character of unit," write: "Worked by lessees on —— per cent of royalty;" insert the percentage charged by the owner to the lessees, specifying whether "gross" or "net," i. e., whether computed on the gross or on the net product. In the next blank space insert the average number of lessees employed.

After the words "Total amount paid for such work" insert the amount received by the lessees out of the total product after deducting treatment and freight charges and royalties. For example, if the gross product reported under Inquiry 10 is $10,000, the net product is $6,000, the rate of royalty 25 per cent net, then the entry in the first blank space should read as follows: "Worked by lessees on 25 per cent royalty, net," and in the last blank space, "$4,500." If the rate of royalty is varying or is not stated, compute the average net rate. For this purpose first obtain the amount of the royalty by subtracting the amount received by the lessees from the total net value of the mining product, and next compute the percentage of royalty to the total net value. In many cases the rate of royalty reported represents the percentage of the lessee's share to the total product; this is an error. If the value of the product is $6,000 and the lessees received $4,500, the rate of royalty is not 75 per cent but 25 per cent, the ratio of the royalty, $1,500, to the total product. If any estimates of wages received by lessees are given under Inquiry 4, they should be erased by drawing red lines through them.

On all such schedules write on the title page in the right margin after the words "Name of the company, etc.," the words "Block lessees." For the sake of uniformity this term should likewise be used in the few cases of placer mines worked on the tribute system, but the words should be in quotation marks.

Mines worked on shares.—If the mine is worked on shares no answer is required to Inquiry 4, but the report under Inquiry 5 must read, "Worked on shares," the number of men so employed should be given in the next blank space.

Inquiry 8.—The answer to this inquiry must not include any expenditures of a permanent nature which has no direct relation to the mine, such as construction of buildings, mills, dwelling houses, etc. If any such expenditure is included, a request for correction should be made, asking that the expense be eliminated. If no answer is made to this inquiry, write the word "None." In some cases the cost of supplies and materials is reported to include also "Miscellaneous expenses," which ought to be reported under Inquiry 9. No segregation should be attempted, but after the words "Miscellaneous expenses" write in red ink "See Inquiry 8."

Inquiry 9—Development work.—The amount reported under this inquiry is, with very few exceptions, also included under Inquiries 4, 7, and 8. In the absence of indications to the contrary, this fact should be noted in red ink, a line should be drawn under the amount expended in development work, and the entire entry should be included in brackets. The amount should not be added with the other items reported under this inquiry, and if it is so added it should be eliminated from the total.

If it appears that the amount reported for development work is not included in the operating expenses, information should be obtained by communicating with the operator for the purpose of apportioning the expenditure under Inquiries 4, 7, and 8. If it is not possible, a note should be made in red ink "Not included in operating expenses." If the amount reported for development work is equal to the total wages and salaries, or total wages alone, or to wages, salaries, and supplies, or wages and supplies, or any of these items in connection with contract work, the item should be erased.

If, however, the amount of development work is equal to the amount paid for contract work alone it should stand.

Expenditures for construction of mills should not be included under "Development work," and the amount so included, if any should be eliminated.

Rent and royalties.—Whenever it appears from the answer to Inquiry 12 that land is held on lease, some rent or royalty should, as a rule, be reported under Inquiry 9. In some cases, however, the consideration for the lease is a certain amount of development work, so that if the report shows an expenditure for the same, but no rent or royalties, the answer may be deemed consistent.

Payments on "bond and lease" are in the nature of payments on a purchase-money mortgage and should be eliminated.

If the answer to Inquiry 15c shows that power was supplied to the mine by another establishment, the rent paid for power should be reported either under "Water rent," or, in case any other power was supplied, under "Other rent or royalties."

If water rent or rent of electric power is included among "Supplies and materials" (Inquiry 8), or in the last item of Inquiry 9 (amount paid for taxes, insurance, etc.), it should be eliminated. If the report does not conform with these requirements, a request for correction must be sent.

Amount paid for taxes, insurance, etc.—If the cost of supplies and materials is included in this item and no report is made under Inquiry 8, the amount so reported should be transferred to Inquiry 8, and a note in red ink should be made reading, "See Inquiry 8."

Total.—The total should always be inserted, even if there is only one item; such item should then be restated as the "Total."

III. Product.

The product is reported on Schedules Nos. 10a and 10b, as the case may be, and on Schedule No. 10, Inquiry 10.

A. PLACER MINES.

Schedule No. 10b—Inquiry 3.—It is intended that the report should give (a) the exact crude weight of the gold product, the total gross value allowed for it by the mint or private party buying the same, and (b) the average fineness of the gold produced. The crude weight multiplied by the average fineness will furnish the total number of fine ounces. (bb) There are very few schedules, however, where this inquiry has been properly answered. In many cases the value alone is given in round figures, which is usually an estimate; sometimes the average fineness is given with it. In such cases a request for correction should be sent, asking the number of crude ounces. In other cases the price paid per crude ounce is given. The number of crude ounces can be obtained by dividing the value by the price per ounce. In such cases the schedule should be criticised with a view to ascertaining the average fineness. In some cases the average fineness reported represents the ratio between the price per crude ounce and the coining value of a fine ounce, viz, $20.67. This is incorrect, as the price paid per ounce is always less than the coining value of the gold; such "fineness" should be disregarded.

In those cases where a complete report is made and the value of the product appears to be less than the coining value, i. e., than the number of fine ounces multiplied by $20.67, the coining value should be substituted for the value reported in answer to Inquiry 3 on Schedule No. 10b as "Gross value," while the amount reported should be erased from Schedule No. 10a and transferred to Schedule No. 10, Inquiry 10, as "Net value of the mining product."

If the number of crude ounces is given and the amount is figured at $20 per ounce, the ounces should be taken as fine and entered on Schedule No. 10b at *bb*. The value should appear on Schedule No. 10, Inquiry 10, both as *gross* and *net*.

If no reliable data showing the number of fine ounces are available, Inquiry 3bb should be left blank. All such schedules should be assorted into a separate group for tabulation.

Schedule No. 10—Inquiry 10.—The gross value of the metallic contents must be equal to the total reported on Schedule No. 10b under Inquiry 5. The "Charges for treatment" should include mint charges, commissions, etc.; the "Freight" represents expressage and insurance on bullion. These questions, however, are hardly ever answered.

The "Net value of the mining product" is usually reported equal to the "Gross value," which is incorrect. Whenever the actual gross value can be obtained, as explained above, the difference between the gross value and the net value will represent the charges for treatment and should be so entered.

In most cases either the gross or the net value alone is reported under Inquiry 10, Schedule No. 10. If this missing item can not be obtained, the amount reported on Schedule No. 10a should be entered on Schedule No. 10 as "Net value of the mining product."

B. DEEP MINES.

Schedule No. 10a—Inquiries 1, 2, and 3.—There should be a complete answer to these three inquiries. If the total quantity of ore mined in 1902 exceeds the total quantity sold or treated during the same year, then the stock on hand December 31, 1902, should exceed by the same quantity the stock on hand December 31, 1901. Conversely, if the quantity sold or treated exceeds the quantity mined there must be a corresponding decrease of the stock on hand.

If the quantity sold or treated is reported the same as the quantity mined, the stock on hand on both dates must be the same.

Very often the stock on hand is not reported at all. In case the quantity sold or treated is the same as the quantity mined, the omission may be disregarded. In case those quantities are not the same, the increase or decrease, as the case may be, should be entered on the reverse side of Schedule No. 10a under Inquiry 12. In order that the total net increase or decrease of the stock of ore on hand should agree with the total stock on hand December 31, 1901, and December 31, 1902, the increase of stock should also be entered under Inquiry 3 as "stock of ore on hand December 31, 1902," while the decrease should be entered under the same inquiry as "stock of ore on hand December 31, 1901."

Inquiry 4—Bullion contents of the ore.—The answer to this inquiry specifies each metal contained in the ore. Enter the name or names of the metals on Schedule No. 10 in the upper corner of the title page, viz, "Gold," or "Silver," or "Copper," or "Lead," or "Gold and silver," or "Silver and lead," or "Gold, silver, and lead," or "Gold, silver, and copper," etc., as the case may be. All schedules have heretofore been marked "Gold and silver;" this designation should be allowed to stand only when it corresponds with the actual contents of the ore, otherwise it should be corrected as above indicated.

Quantity.—Gold and silver must be given in fine ounces, copper and lead in pounds.

If iron, zinc, or manganese is contained in the ore, the quantity must be reported, even though no allowance may have been made for it in the value of the ore.

In some cases the answer, instead of giving the total quantity of each metal contained in the product reported, states only the contents per ton. In such cases the contents so reported should be multiplied by the number of tons sold or treated and the totals inserted where they belong.

Base metals are sometimes given in percentages. In such cases the quantity can easily be computed. Usually in adjusting the price of the ore a discount or allowance is made for losses in smelting; as a result, in many cases the quantity reported is the net quantity for which payment was received, instead of the total contents of the ore as shown by assay. This is incorrect, and wherever the fact is disclosed the schedule should be corrected by inserting the actual contents of the ore instead of those for which payment was received. If the actual contents can not be calculated, a request for correction should be addressed to the operator. The value of the product should, however, not be changed.

Value.—The value of each metal ought to be reported by the operator. It should in every case be the value actually allowed to him by the smelter or ore buyer. Only where it is impossible to obtain a report from the operator should the averages of the United States Geological Survey be accepted as substitutes.

The United States Geological Survey, in its tabulation, discards the values reported by the operators and substitutes, in lieu of them, uniform average prices, viz, $20.67 per ounce of gold fine, $0.52 per ounce of silver, $0.11 per pound of copper, and $0.04 per pound of lead.

These averages represent the coining value of refined gold and the annual average New York quotation of all other metals. While the New York quotation of silver is often taken as a basis of settlement for ores, yet there are few schedules, if any, where the value reported by the operator for copper and lead approximates the New York quotation. Copper is usually reported at 5 and 6 cents per pound, instead of 11 cents, as accepted by the United States Geological Survey. Lead is usually reported at 1½ to 2 cents per pound instead of 4 cents. Some of the largest buyers in the United States allow a uniform price of 3½ cents per pound from which 2 cents per pound are deducted for freight from Salt Lake City to New York. Thus actually the net price paid is 1½ cents per pound.

Whenever the average value per ounce of gold is less than $19 the presumption is that the ounces are not fine, but crude; in such case the schedule should be criticised.

The price for silver in 1902 was subject to considerable fluctuations; the highest price did not exceed 56 cents. If the price reported by the operator is in excess of this rate, the schedule should be criticised.

Value alone reported.—When the values alone of the bullion contents are reported but not the quantities, a request for correction should be made. If it is impossible to obtain these data directly from the operator, the quantity should be estimated at this office. In such cases Schedule No. 10, Inquiry 11, should be consulted. If the address of the reduction works is given to which the ore was sold, the rate at which each metal was paid for should be obtained from the report of the respective mill or smelter. If such information is not available, then the quantities should be estimated on the basis of the United States Geological Survey averages.

Schedule No. 10, Inquiry 10—Gross value of the metallic contents as reported to the United States Geological Survey.—This value should be equal to the total value on Schedule No. 10a.

DEDUCTIONS.

The deductions consist of the following items:

Discounts.—As has been explained above, very frequently a discount is made for losses in smelting. Thus the price per ounce of gold is made $20, but 5 per cent is deducted as a discount, bringing the actual price down to $19. Some operators will report the value of gold at $20 and charge off a corresponding amount under "Discounts." Similarly, some will report discounts on silver and lead. Whenever such discounts are reported separately, they should be preserved under "Deductions," to be subsequently tabulated.

Very frequently only one amount is reported for discounts. No segregation of the discounts need be made in such cases.

Charges for treatment.—This item ought to include charges for sampling, assaying, and milling or smelting. If these several charges are reported separately, they should be combined into one item. *In such cases a memorandum giving the name of the mine and mining company, the state and county, should be made and delivered to the expert special agent in charge.* Usually the treatment charges include also discounts. If the latter are not reported separately no segregation should be attempted, but the amount should stand as reported.

In some cases the treatment charges include freight charges. The amount reported should be allowed to stand; no segregation need be made.

Freight charges.—These include the cost of packing and haulage by team and railroad freight.

When the two items are reported separately, they should be allowed to stand.

Charges and freight per ton.—Besides the total charges, the inquiry calls also for charges and freight per ton. The latter can be given only when every shipment of ore was treated at one establishment.

It frequently happens, however, that the ore is first concentrated at a custom mill and the concentrates are then shipped to a smelter. The tonnage shipped to the mill is then quite different from that shipped to the smelter; average rates per ton would in such cases be misleading and should be erased. *All such schedules should be referred to the expert special agent in charge.*

No charges.—In many cases the full value of the gold and silver contents of the ore is paid to the operator, no charges whatever being made for treatment and freight; this is when the ore contains a high percentage of iron and manganese, which are not paid for. Sometimes the percentages of iron and manganese are so high that a bonus is paid to the mine operator, besides free treatment and freight. The amount of the bonus should be entered on Schedule No. 10a, Inquiry 4, as the value of the iron or manganese.

NET VALUE OF THE MINING PRODUCT.

The net value of the mining product is equal to the gross value less the deduction for treatment charges and freight.

In some cases the question was misunderstood, and the net profits were reported instead of the net value of the product. The amount should be properly corrected.

In many cases nothing but the net value of the mining product is reported by the operator; it is when the ore was sold "at a flat price per ton." In such cases, if the metallic contents are reported on Schedule No. 10a, Inquiry 4, the total value, as calculated by the United States Geological Survey, should be accepted as the "gross value," the net amount received by the operator as the "net value," and the difference should be entered under "Deductions."

HIGH-GRADE AND LOW-GRADE ORES.

Schedule No. 10a, Inquiry 11.—Divide the total contents of gold and silver given under Inquiry 4 by the total quantity given under Inquiry 2; enter the results under gold and silver. Compute in the same manner the number of pounds of copper, lead, and other metals per ton, and, further, divide each quotient by the number 20, which will give the percentage of copper, lead, etc.; enter the same in the proper places.

Divide the total value given under Inquiry 4 by the amount of ore sold or treated given under Inquiry 2. Enter the result under "aggregate gross value."

If the "aggregate gross value" is less than $10, it is "low-grade ore," if more than $10, it is "high grade." The designations "high grade" or "low grade," as the case may be, must be written on the title page of Schedule No. 10 in the blank space after "character of ore."

INCREASE OR DECREASE OF THE STOCK OF ORE.

Schedule No. 10a, Inquiry 12.—Deduct the stock on hand December 31, 1901, from that of December 31, 1902, or vice versa, and enter the difference under increase or decrease.

Divide the "net value of the mining product," given on Schedule No. 10, Inquiry 10, by the number of tons sold or treated and multiply the difference by the increase or decrease of the stock of ore on hand.

TOTAL ESTIMATED VALUE OF THE MINING PRODUCT.

Schedule No. 10a, Inquiry 13.—Add the estimated value of the increase of stock, entered under Inquiry 12, to the net value of the mining product, as given under Inquiry 10 on Schedule No. 10, or deduct the estimated value of the decrease of stock from the net value of the mining product. Enter the result as the "total estimated value of the mining product."

IV. NAME AND ADDRESS OF MILL OR WORKS AT WHICH THE ORE IS TREATED.

Schedule No. 10, Inquiry 11.—The answer to this inquiry should indicate the disposition made of the ore, whether it was *sold*, or *treated at the company's reduction works, or treated at a custom mill.* When the ore is treated for the account of the mine operator at a mill directly connected with the mine, the fact should be stated; if not stated, it will appear from the accompanying Schedule No. 11, and the answer should be supplied at this office in terms identical with the underlined phrases above.

If the address of a mill or smelter is given, but the report fails to state whether the ore was sold or treated on tolls, the character of the mill should be ascertained by references to the schedule whereon it is reported. If it proves to be one which both buys ores and treats them for the customer's account, the answer to Inquiry 4, on Schedule No. 10a, will ordinarily be reported in crude ounces, which will appear from the low valuation of the gold. *In cases of uncertainty the schedule should be referred to the expert special agent.*

V. PROCESS OF TREATMENT.

Schedule No. 10, Inquiry 11; Schedule No. 10a, Inquiries 8 and 10.—All ores are classified according to process of treatment into *milling* and *smelting ores.* The process of treatment will appear from the answers to Inquiries 8 and 10, on Schedule No. 10a, or Inquiry 11, on Schedule No. 10.

If the ore is concentrated and then smelted, it should be classed as a milling ore.

The designation "milling" or "smelting" should be written on the title-page of Schedule No. 10, in the line reserved for "character of ore."

Arrastra of mine.—No Schedule No. 11 is required for "arrastras," but all reports for mines connected with arrastras should be segregated into a separate group.

Reduction of ores by hand.—In a number of small mines the ore is reduced by hand in a mortar. All reports for such mines should be assorted into a separate group.

VI. MINERAL LANDS.

If the dimensions of the claim are reported instead of the acreage, the latter should be computed. If the number of mineral claims is reported, the acreage should likewise be computed by multiplying the number of claims by the average size of the claim as determined by law. If the report shows no land owned and some held on lease, a note should be made on the title-page, in the upper right-hand margin, reading "lessee's report."

VII. REDUCTION WORKS.

Reduction works have been divided for census purposes into *smelters* and *reduction works other than smelters*, or mills, the former being reported on Schedule No. 12, the latter on Schedule No. 11 and 11a or 11b.

All smelter reports must be referred to the expert special agent in charge. In some cases smelters were erroneously reported on Schedule No. 11. Such schedules should likewise be referred to the expert special agent, together with all Schedules No. 10 relating to mines connected with smelters.

All mills are to be divided for tabulation purposes into two classes, (1) mills without mine connection, commonly designated as "custom mills," and (2) mills connected with mines.

A. CUSTOM MILLS.

Reduction works, other than smelters, without a mine connection are reported on Schedules No. 11 and No. 11b.

Inquiries 1, 2, 3, 7, and 11 are substantially identical with Inquiries 1, 3, 6, 8, and 15, respectively, on Schedule No. 10. (See instructions above.)

Inquiry 3 on Schedule No. 11 corresponds to Inquiry 4 on Schedule No. 10, except that the division "below ground" is absent.

Inquiry 8 on Schedule No. 11 corresponds to Inquiry 9 on Schedule No. 10, with the omission of "development work," and of the detailed inquiry into rent or royalties.

Inquiry 12 serves the same purpose as Inquiry 11 on Schedule No. 10.

Inquiry 6—Materials bought in 1902.—This inquiry is in form a combination of Inquiry 4 on Schedule No. 10a and Inquiry 10 on Schedule No. 10, and is intended to bring out the same information, but from the standpoint of the mill owner. (See instructions above.)

Nothing but materials bought should be reported under this inquiry. The values to be reported under this inquiry are those contained in the ore before treatment and are not identical with the values extracted, which are reported on Schedule No. 11a; with the best methods known a portion of the contents is lost in the residue, or "tailings." If, therefore, the assay contents reported appear to be identical with the final product reported, a request for correction should be made.

The "working charges" are those made by the owner of the reduction works on the ore bought by him, and not those deducted from the value of his bullion or concentrates by the mint, smelter, or sampler buying the same. The charges on the final mill product must be reported under Inquiries 5 or 9. In case the answer to Inquiry 6 duplicates in this particular the answer to Inquiry 5 or Inquiry 9, a request for correction should be made. Nor are these charges identical with those under Inquiry 10, which relate to "custom work," i. e., to the treatment of ores for patrons' account, and not to ores bought by the mill.

PRODUCT.

The gross value of the mill product is reported on Schedule No. 11b, under the head of "Production," and transferred therefrom to

Inquiry 9 on Schedule No. 11, as "gross value of metallic contents as reported to the Geological Survey." The inquiry is so worded as to include both the product of *purchased ores* and of those *treated for customers' account.* In actual practice, however, few mills reported the product of custom ores, stating that the bullion or concentrates were returned to owners and no record thereof was kept at the works, except the tonnage treated and the amount received for treatment. In those few cases where the contents of custom ores are given they are confessedly more or less loose estimates, with hardly any exceptions. For the sake of uniformity of results nothing but the product of purchased ores should be allowed to stand under the head of production.

In case no ores were purchased the fact will appear from the answer to Inquiry 6 on Schedule No. 11. In all such cases the total quantity under "Production" on Schedule No. 11b must be identical with that reported under Inquiry 10 on Schedule No. 11. The "total yield in gold," "total yield in silver," copper, lead, and other metals, if reported, should be crossed out and the word "None" should be inserted; likewise should the word "None" be inserted under Inquiry 9 on Schedule No. 11. But the same amounts under "sources of materials treated" should not be disturbed.

In case the mill handled both purchased and custom ores, a comparison of Inquiries 6, 9, and 10 on Schedule No. 11, and "production" and "sources of materials treated" on Schedule No. 11a will assist in determining the product of purchased ores alone. In case of uncertainty a request for correction should be sent.

For particulars in relation to the several items of the yield from purchased ores (gold, silver, lead, copper, etc.), see instruction above for mining product.

Treatment and freight charges.—The milling product requires further treatment at a mint, refinery, or smelter. Usually the product is sold, sometimes it is treated on tolls for the account of the mill owner. In the former case the deductions from the gross value of the product should be reported under Inquiry 9, in the latter case under Inquiry 5.

Sometimes the same amounts are duplicated under Inquiries 5 and 9. In such cases it may be safely assumed that the product was sold, and the answer to Inquiry 5 should be erased. When no purchased ores were treated at the mill, the answer to Inquiries 5 and 9 should be "None." For further particulars see above instructions for "Mines."

CUSTOM WORK.

Schedule No. 11, Inquiry 10.—The "amount received" should represent the mill charges for the work of the mill, not the value realized by the customer from the sale of his bullion.

Sources of material treated—Schedule No. 11b.—In a very few schedules this inquiry has been answered. The answer should be supplied at this office. Transfer the tonnage and values given under "Productions" to Inquiry B, on the reverse side of Schedule No. 11b, entering the same under "Total domestic."

If the inquiry is answered, transfer likewise the values to Inquiry B, entering them under "Total domestic" or "Total foreign," as the case may be; for the tonnage repeat that given under "Production."

Schedule No. 11b, Inquiry A—Bullion contents, assay contents before treatment, and average value per ton of product from purchased materials.—Divide the amounts given under "Production" by the quantity of ore treated given under the same inquiry; further divide the quotients for the base metals by the number 20; enter the results in the first column.

Divide the "gross value of the metallic contents, etc.," given on Schedule No. 11, under Inquiry 9, by the same quantity of ore, as above, and enter in the space below for "average value per ton."

Divide likewise the assay contents and total gross value of all materials reported on Schedule No. 11, under Inquiry 6, and enter the results in the second column.

B. MINES CONNECTED WITH REDUCTION WORKS.

In accordance with the classification of reduction works into "smelters" and "other than smelters" (mills), mines will be found connected with smelters or mills.

The number of mines connected with smelters is very limited. The reports for such mines should be attached to the smelter reports and referred to the expert special agent for separate treatment.

Where a mine and reduction works are operated under the same management, separate reports were requested for each on Schedules Nos. 10 and 11. But where this was not possible (because the accounts for the mine and the mill were not kept separately) one report was requested covering both the mine and mill. Inquiries on Schedule No. 10 were to be answered, except Inquiry 10, and answers were also to be given to Inquiries 4, 5, 9, 10, and 12 on Schedule No. 11.

Most of the schedules which have been received report both the mine and the mill together; there are, however, a considerable number of schedules where the mine and mill are reported separately; a further number of separate schedules for reduction works have been prepared at this office from printed annual reports furnished by the mining companies. Accordingly, all schedules should be assorted into two classes: (1) Those where the mine and the reduction works are reported separately, (2) those where they are reported together.

1. *Separate reports from mine and mill.*

In examining the former, the instructions should be followed which have been laid down for separate mine and mill reports, except that Inquiries 1 and 2 on Schedule No. 11 should be left blank.

Similar to these reports are those where *all inquiries relating to the mine and reduction works are answered separately, except those relating to production, viz,* Inquiry 10 on Schedule No. 10 and Inquiry 9 on Schedule No. 11, which are duplicated. The answer to Inquiry 10 on Schedule No. 10 should in such cases be crossed out.

Hauling from mine to mill.—If the mill is at a considerable distance from the mine, the cost of hauling the ore from the mine to the mill is very frequently reported on Schedule No. 10 under Inquiry 10. In all such cases this item should be allowed to stand, and should not be transferred to Inquiry 9 on Schedule No. 11.

Power.—In some cases Inquiry 11 on Schedule No. 11 is answered. It must be ascertained whether it contains no duplication of the power reported on Schedule No. 10. If there is no duplication, the answer should be allowed to stand.

2. *One report for both mine and mill.*

Where only one report is made for the mine and reduction works, all instructions relating to each schedule should be followed as far as applicable.

Mill supplies.—Where one report only is made for the mine and the mill, Inquiry 7 on *Schedule No. 11* is sometimes answered. In such cases the cost of mill supplies so reported should be transferred to Inquiry 8 on Schedule No. 10.

Schedules Nos. 10a and 11a.—If the mill is confined to the treatment of the product of the mine, the report on Schedule No. 11a will be a duplication of that on Schedule No. 10a. The former shall, in all such cases, be crossed out, with a note reading "See Schedule No. 10a."

Concentrates.—If the process of treatment includes concentration, the number of tons of concentrates produced should be entered on Schedule No. 11a, in the blank space reserved for "total quantity of products other than bullion." The word "concentrates" should be inserted in red ink.

3. *Milling and smelting ores.*

It is a common practice to assort the ores into "first class" ores, which are shipped to the smelter, and low-grade ores, which will not

stand the expense of transportation and must be treated at the mine. In such cases the product should be reported as follows:

Schedule No. 10a, Inquiry 2.—The "total quantity of ore sold or treated in 1902" must be divided into "ore sold" and "ore treated" and each quantity stated separately on the right margin.

Inquiry 4.—The answer to this inquiry should give nothing but the ore *sold;* the words "or treated" should be erased.

Schedule No. 11a.—The bullion contents of the ore treated at the mill must be reported on this schedule. The quantity of concentrates, if any, should be reported in the manner explained above.

Schedule No. 10, Inquiry 10.—The gross value, deductions, and net value of the mining product under this inquiry should be confined to the product sold. A note should be made in each case, reading "see also Schedule No. 11, Inquiry 9."

Schedule No. 11, Inquiry 9.—The gross value, deductions, and net value of milling product under this inquiry should be confined to the product treated at the mill.

All such schedules must be segregated into a separate group

4. *Calculations.*

The answers to the following inquiries on the back of Schedule No. 11a must be supplied at this office:

Inquiry 1.—Bullion contents and gross value per ton of ore mined and milled.

If the bullion is all from ores mined by the same company, divide the bullion contents of the precious metals, given on Schedule No. 10a under Inquiry 4, by the total amount of ore treated, given on Schedule No. 10a under Inquiry 2; the result will give the number of fine ounces of gold and silver per ton. Divide the total copper, lead, and other base metallic contents by the same tonnage treated, and further divide the result by 20; the quotients will give the percentages of lead, copper, etc., in the ore. Divide the total value given under the same head by the same tonnage; enter the quotient under aggregate gross value.

Inquiry 2.—If the bullion is partly from ore mined by the company, partly from purchased ores, the quantities and values given on Schedule No. 11a must exceed those on Schedule No. 10a under Inquiry 4. Deduct the latter from the former; enter the differences in the first and third columns, respectively.

Divide the amounts entered in the first column by the total tonnage reported on Schedule No. 11a under Inquiry 6; divide further the figures for base metals by the number 20; enter the results in the second column.

Divide the total gross value of the third column by the same tonnage and enter in the same column on the line intended for "average per ton."

Similarly, divide the "total assay contents" and "total gross value" reported on Schedule No. 11 under Inquiry 6 and enter the results in the fourth column.

Inquiry 6.—Copy the items entered on the face of this schedule under "Sources of materials treated in 1902." Add separately all domestic and all foreign material and enter the totals on this schedule.

All schedules reporting foreign ores treated must be brought to the attention of the expert special agent.

5. *Placers with stamp mills.*

As a rule, only the product of deep mines requires further treatment at reduction works. The product of placer mines is gold dust or amalgam, which can be sold to a United States mint or assay office, or to a private refinery. In some cases, however, the placer ground is cement, which must be crushed in order to wash out the gold. This is done in a stamp mill. Accordingly, there are a few reports on placer mines with reduction works. These should also be segregated into a separate group.

6. *Old mine dumps and old mill tailings.*

A separate class is formed by those mills which treat low grade ore from old mine dumps or old mill tailings, which could not be profitably treated with the old methods. In every case of this kind the report on Schedule No. 11 and 11b should be supplemented by one on Schedule No. 10, giving the rent or royalties under Inquiry 10. These supplemental schedules must be prepared at this office. Where the method of treatment is concentration, a Schedule No. 11a should also be prepared in the manner indicated on a subsequent page.

The reports for old dumps and old tailings should be assorted into two separate groups.

INSTRUCTIONS FOR VERIFYING AND CORRECTING THE LABOR AND WAGE INQUIRY ON THE MINING SCHEDULE.

As a general rule, the amount of wages and the specified daily rates reported should be accepted as correct. The main object of the revision of this inquiry should be to harmonize the average number of wage-earners, as returned in the several classes under No. 3, employed during the year and the average number of wage-earners at specified daily rates of pay with the amounts reported for each class of employees, the rates of pay, and the time employed.

In revising the number of wage-earners of the several classes the following rules should be followed:

Multiply separately the minimum and maximum of each daily rate under which employees are reported by the number of employees; then multiply each product obtained by the number of days in operation. The results will show the lowest and the highest amounts that could be received as wages. The results obtained by this calculation should be compared with the amount of wages reported for each class of employees under the first section of the inquiry.

If the computation shows that the amount of wages reported for the different classes is within the maximum and minimum, the number of each class of employees should be considered as the correct average number for the time in operation.

If the schedule is properly filled out, the minimum amount (as derived from the above computations) can not be more, nor the maximum amount less, than the actual amount of wages as reported in the first section of the inquiry. Frequent exceptions to this will be found in the class of engineers, firemen, machinists, etc. These employees usually work full time, and there should be no revision of the average number if the amount of wages reported is equal to the amount obtained by the computations of the minimum daily rates multiplied by 300 days. If the amount of wages reported is less than the result obtained by this computation, the revision should be made in the usual manner.

The average number of miners, quarrymen, boys, and all other classes of wage-earners, however, should in all cases be revised to agree with the daily rates and the number of days in operation, giving due consideration, of course, to the fact that certain classes of employees, as a rule, work a larger number of days than others, particularly if the mine does not work the entire number of days in the year.

In reducing the average number of each class of workmen to the average by the year, the basis on which the reduction should be made is the number of days in operation. *Having ascertained the average number of each class of workmen for the number of days in operation, this number should be reduced in the proportion that the number of days in operation is of the entire number of working days in the year, which should be considered as 300.* The following is an example: Number of quarrymen and stonecutters reported, 6, which is the average for the number of days in operation, 250: $\frac{250}{300} \times 6 = 5$, which is the average of employees for the entire year. Should there be any fractional remainder, the following will serve as an example of the method of revision: Number of miners reported

98, which is the average for the number of days in operation, 178: $\frac{178}{300} \times 98 = 58.14$, or cutting off the second decimal place, 58.1. In all cases where the average number of wage-earners is less than one, the fraction should be preceded by a cipher, as for instance, "0.9."

Both in the first and second sections of the wage inquiry the average number of wage-earners should be carried out to one decimal place and the corrected figures entered plainly on the schedule in red ink, the old figures being crossed out. This reduction should not be made in the salaried employees.

Where the minimum wages is greater than the actual wages paid, the average number should be reduced to the number that would earn the wages given at the minimum rate; or, should the maximum wages be less than the actual wages paid, the average number should be increased to the number that would earn the wages given at the maximum rate.

In reducing or increasing the number of hands in the second section of the inquiry, specified daily rates, the number to be deducted or added should be taken from the different daily rates, in the same proportion as the original number at each rate is to the total number of the class under consideration.

Another question that should be considered in this connection is the average number of wage-earners employed during each month. As the schedules are originally reported, the number of each class under the first section of the inquiry is usually the actual number employed while the mine was in operation. The average number of all classes of wage-earners for census purposes is the result obtained by dividing the total of the numbers reported for each month by 12.

An apparent contradiction will sometimes be noted between the number of days in operation and the third section of the wage inquiry, showing the average number employed during each month. For example, the full number of employees may be reported for 12 months, while the number of days in operation may be 250. This may be explained by the fact that the idle days were distributed throughout the 12 months, and in such cases the number of days should be accepted as correct, if consistent with the average number of wage-earners and the amount paid.

If the number of days in operation is in excess of the working days in the number of months reported in the third section, the number of months should be revised to equal as nearly as possible the days in operation. For example, the number of months may have been reported as 7, or 175 days, while the number of days is reported as 240. In this case the number of months should be increased to 9, or 225 days at 25 days per month.

Having revised and corrected the average number of wage-earners in the first and second sections of the inquiry, the average number reported each month should be added and the total divided by 12; if the result is different from the total average number of wage-earners, as revised, in the first and second sections, it should be made to agree by changing the average number for each month in the proportion that each is of the total.
